The advent of herding practices remains a key event in human societies in terms of social, cultural, economical changes and regarding their interactions with animals.

In Africa, no remain of wild ancestors species of sheep *Ovis aries* nor goat *Capra hircus* has never been reported. This suggests that those domestic species have been introduced from the epicentre of their domestication : the Near East^[1].

The first occurrences of those animals remains in the archaeological record are attested since the 7th millennium BCE in Egypt and Lybia^[2].

But their appearance in the Southern part of the continent is only dated to the 2nd century BCE [3].

The modalities of their diffusion across the continent in such large amount of time is still debated : cultural diffusion (percolation) or population migrations; Eastern or Western route?

Regarding the strong evidences of extant exchanges between Eastern and Southern Africa, we propose to document the hypothesis of the Eastern route using biomolecular approaches through a larger project (Fig. 1). Here, we will focus on methodological developments of palaeoproteomics in the context of African remains.

Because of the strong morphological similarities between the caprines species and with other small wild bovids, emphasized by the African burying conditions, the distinction of archaeological remains is not always possible.

We aimed to use a novel biomolecular method for species determination of archaeological material: palaeoproteomics (Fig. 2).

Based on the amino acid variations on preserved proteins, this method allow species identification of remains where DNA might not be conserved, due to increased diagenetic processes amplified by arid environmental conditions.

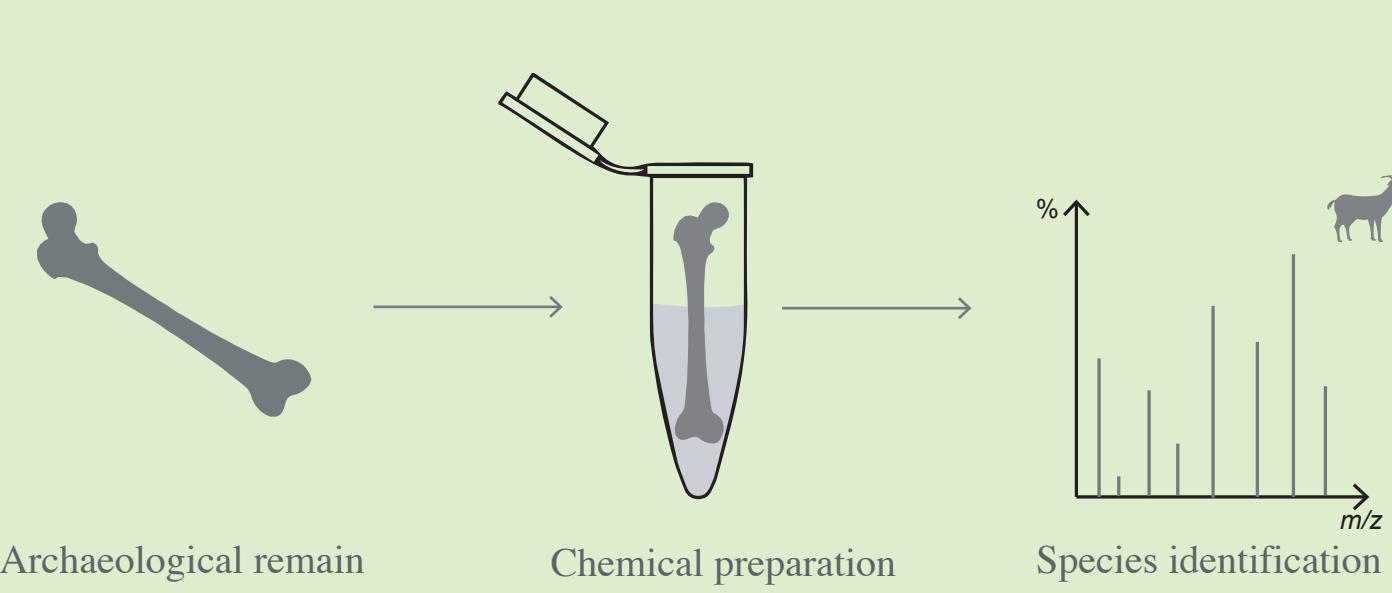

Fig. 2: General principle of palaeoproteomics analyses on archaeological material

and examined by one of the authors (JL). Most of them were too fragmented and altered to propose morphological identifications beyond family^[8].

Estimation of remains organic phase preservation

In order to estimate the organic content of Toteng remains, 0.5 mg of powdered sample were applied on the diamond of a Attenuated Total Reflectance Fourier transform infra-red spectrometer. Anvil pressure was adjusted to normalise $\nu_3\text{PO}_4$ band to an absorbance of 0.5 (Fig. 3).

The ratio between amide I and PO_4 bands area is then used to estimate nitrogen and collagen weight percent content (%wt) according to a method described by Lebon and collaborators^[9].

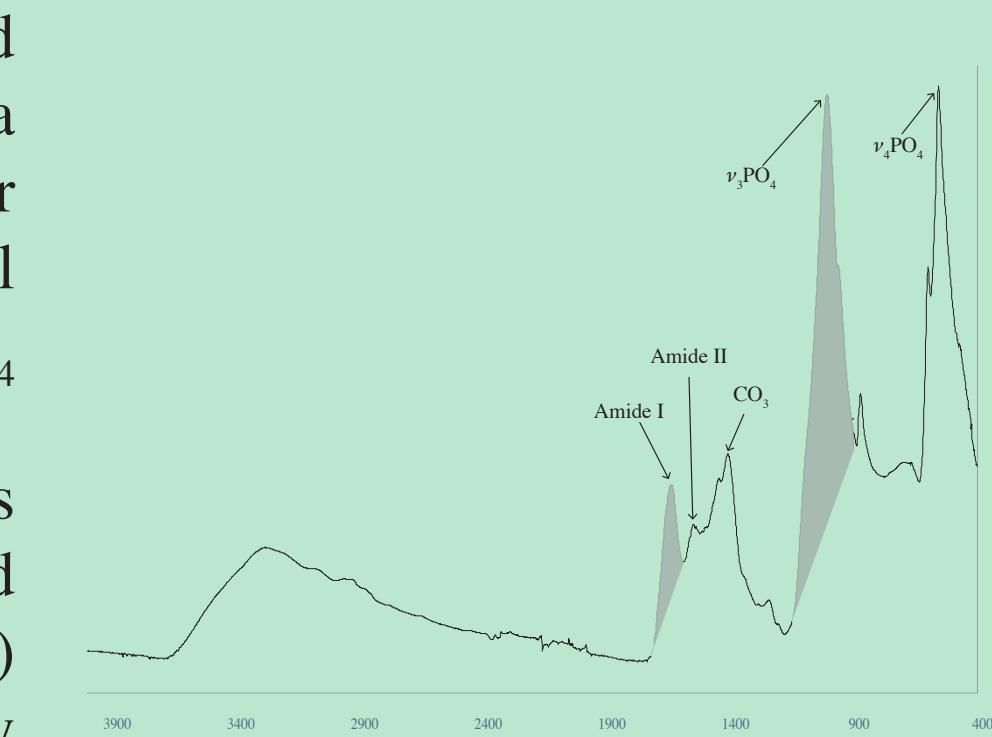

Fig. 3: ATR FT-IR spectrum of a modern bone reference (*B. taurus*). Areas used for organic content preservation estimation appear in grey.

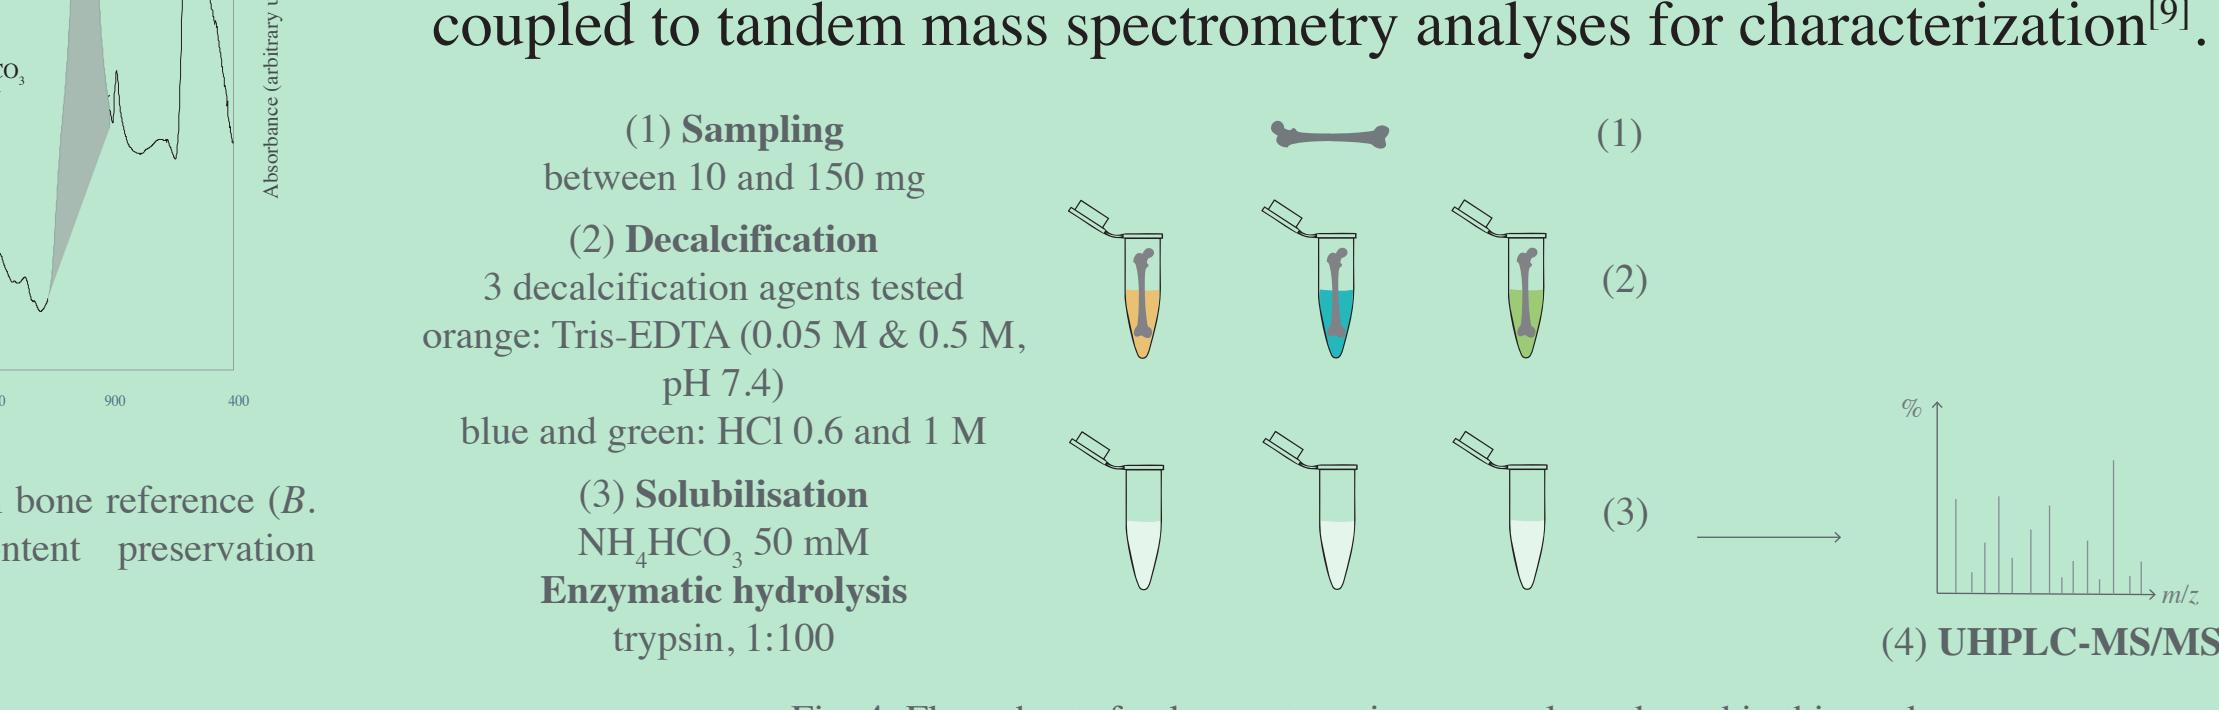

Fig. 4: Flow chart of palaeoproteomics protocol conducted in this study

Abstract
Conclusion
A collagen content threshold of ~ 3 wt% under which it would be risky to perform palaeoproteomics analyses is proposed.

Results

Best suited protocol for remains from arid environments

All 18 Toteng remains presented contrasted organic phase preservation. Nine out of the 18 were selected for palaeoproteomics analyses regarding a range of preservation distributed between 1.91% and 5.38%^[8] of collagen content.

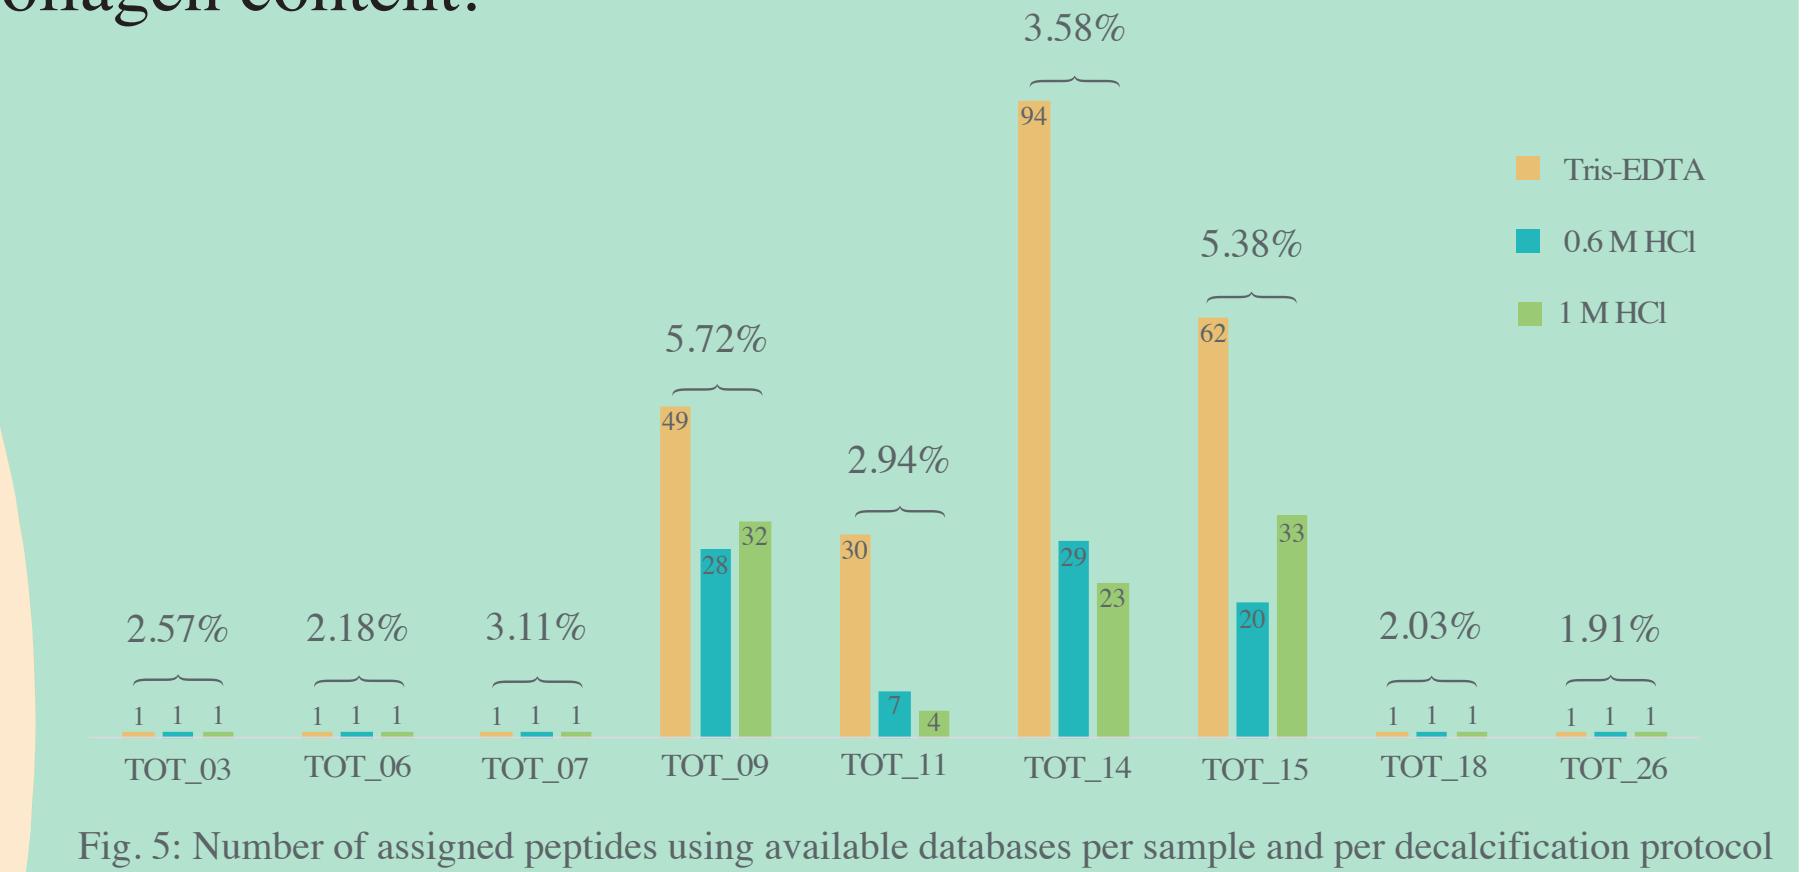

Fig. 5: Number of assigned peptides using available databases per sample and per decalcification protocol used. Preserved collagen content (coll. wt%) are presented above each sample.

Within the nine tested remains for palaeoproteomics analyses, four yielded preserved peptides that were assigned to proteins using available databases (Fig. 5). Identified remaining proteins were $\alpha 1$ and $\alpha 2$ chains of collagen type I. Tris-EDTA buffer allowed the best protein sequence coverage.

Species identification based on protein characterisation

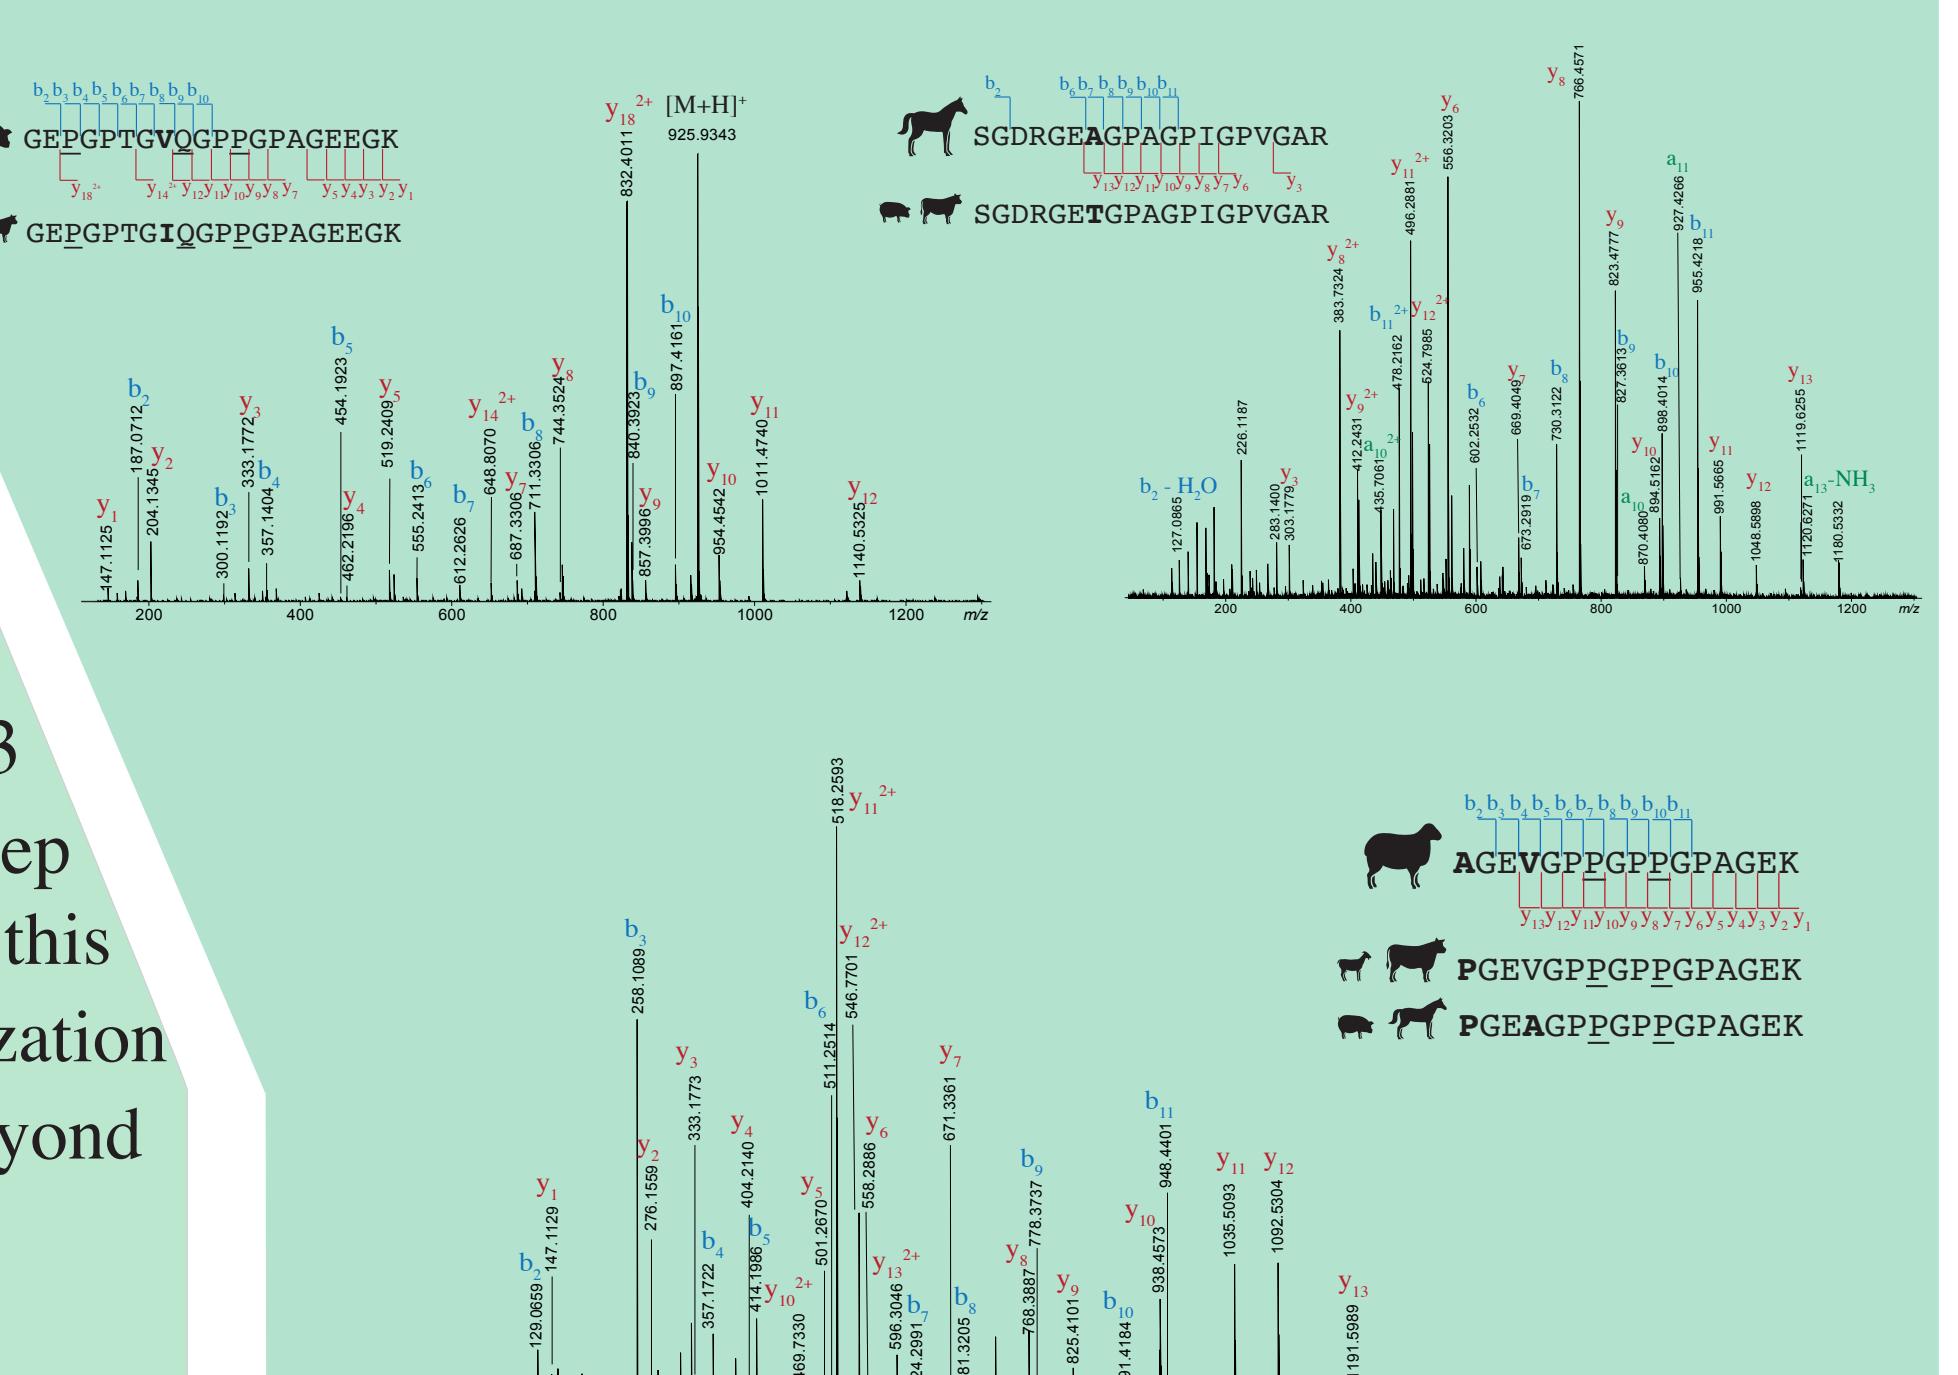

Fig. 6: MS/MS spectra of family and species markers of alpha 1 chain of collagen type I preserved in Toteng samples and identified in this study.

A1 chain of collagen type I allowed the refining of species identification. One remain presented the suidæ marker (Fig. 6, top left), two other the equidæ marker (top right) and one remain was attributed to the domestic caprine species, *Ovis aries* (bottom center)^[8].

All the $\alpha 1$ chain of collagen type I markers presented here were never reported in the litterature and will allow species identification based on the least changing chain of this type of collagen.
