# Modeling the growth of tomato fruits based on enzyme activity profiles

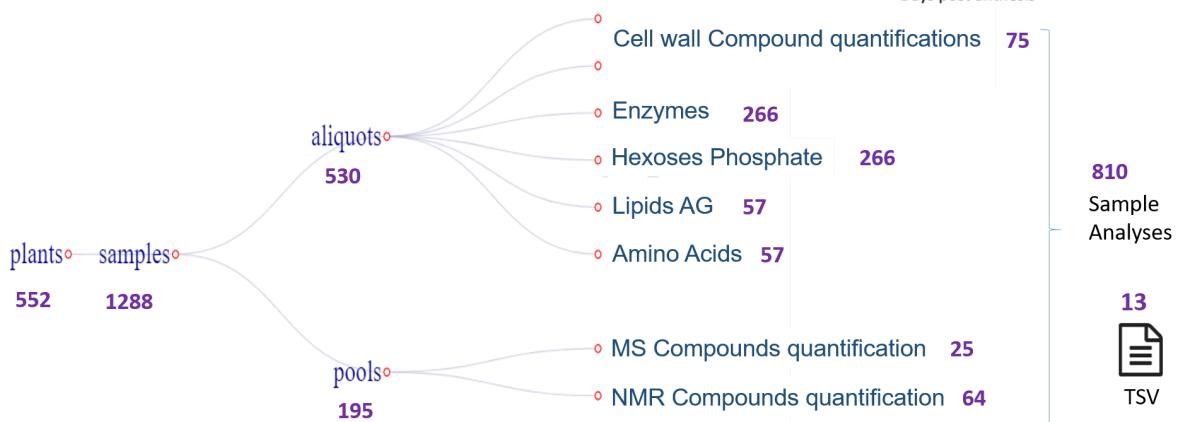

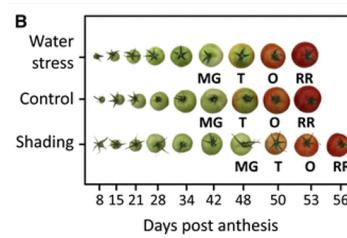

Daniel Jacob - UMR1332 Fruit Biology and Pathology && Bordeaux Metabolome Facility at INRAE

## FRIM data analysis interfaced by ODAM

To assess the influence of the environment on fruit metabolism, tomato (*Solanum lycopersicum* ‘Moneymaker’) plants were grown under contrasting conditions (optimal for commercial, water limited, or shaded production) and locations. Samples were harvested at nine stages of development, and 36 enzyme activities of central metabolism were measured as well as protein, starch, and major metabolites, such as hexoses, sucrose, organic acids, and amino acids.

- 580 tomato plants were grown in a greenhouse in the southwest of France (Sainte-Livrade sur Lot - 2010)
- Fruits were harvested on 3 different trusses (5–7) and at 9 stages of development.
- Treatment - 3 levels : Control, Water stress, Shading

## Modelisation of the plant growth

Analysing and modelling plant growth is an important interdisciplinary field of plant science. The use of relative growth rates, involving the analysis of plant growth relative to plant size, has more or less independently emerged in different research groups and at different times and has provided powerful tools for assessing the growth performance and growth efficiency of plants and plant populations.

To measure the bioproduction of a plant, the component of immediate interest is the net primary production or total yield. The plant weight — usually the dry weight - is a needed measurements for growth analysis. First we have to model the plant growth. The optimization parameters are based on a [Levenberg-Marquardt algorithm](#).

### NLS problems with the Levenberg-Marquardt algorithm

- The purpose nlsLM is to minimize the sum square of the vector returned by the function fn, by a modification of the Levenberg-Marquardt algorithm
- <https://www.rdocumentation.org/packages/minpack.lm/versions/1.2-1/topics/nlsLM>

## Models

- Models : Weight = f(time-dependent .i.e Day After Anthesis)

## Model 1 - Single Sigmoidal Model

$$\bullet \quad f(t) = d + \frac{a}{1+e^{-b(t-c)}}$$

## Model 2 - Sum of two Sigmoidal Model

$$\bullet \quad f(t) = d + \frac{a}{1+e^{-b(t-c)}} + \frac{f}{1+e^{-g(t-h)}}$$

- Performance of the modelisation

```
[6] set.seed(1674)

# Sample subset name
setName <- 'samples'

# Time variable for applying the modelisation
Tname <- 'FruitAge'

# Y variable for applying the modelisation
Yname <- 'FruitDW'

# Additional condition
condition <- 'treatment/Control'

# Performance of the modelisation
system.time( fitObj <- fitSigmoid(dh, setName, Tname, Yname,
condition, model=1, info=TRUE) )
```

Getting ... Fitting ... R2 = 0.9496223 OK

user system elapsed  
0.30 0.00 1.75

- Print the coefficients of the model

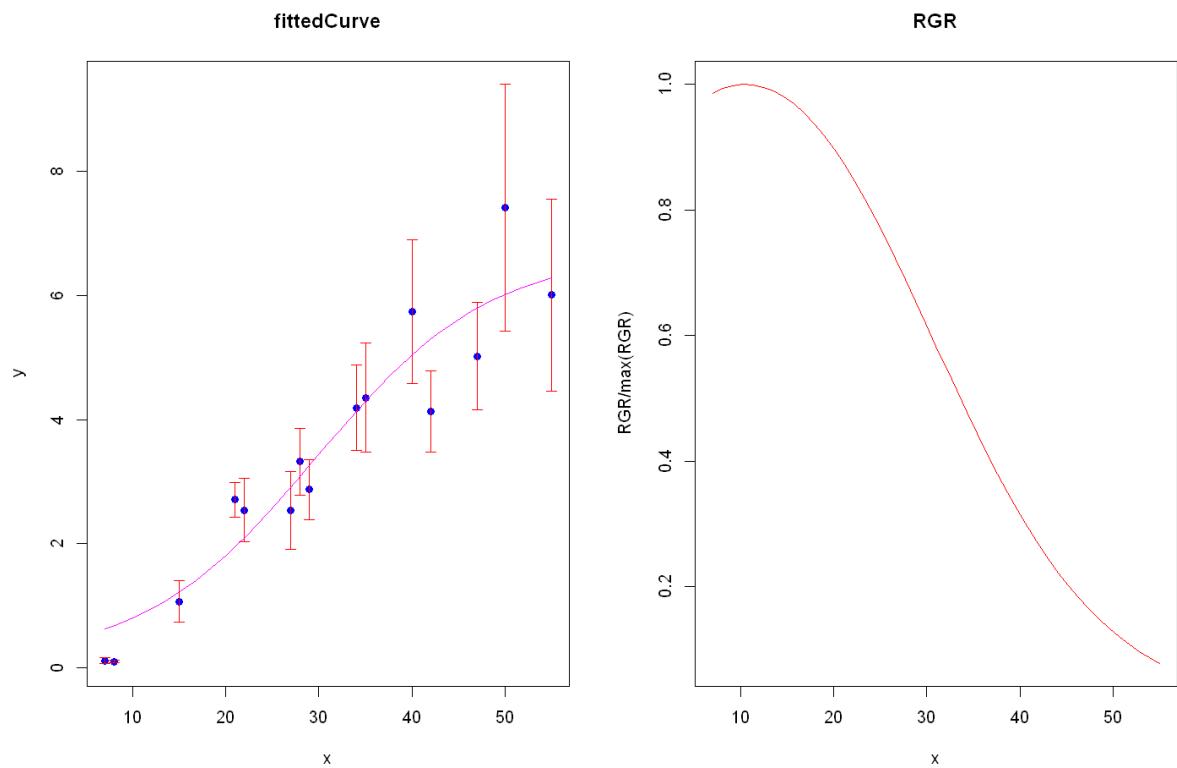

```
[7] print_fittedParams(fitObj)
```

Single Sigmoid  
a b c d

1 6.584323 0.1076615 29.77704 0.1051375

- Plot both 'RGR' & 'Weigth' curves

```
[8] options(repr.plot.width=12, repr.plot.height=8)
par(mfrow=c(1,2))
plot_fittedCurve(fitObj)
plot_RGRCurve(fitObj)
```

## Explanation of the Relative Growth Rate (RGR)

Relative growth rate is a standardised measure of growth with the benefit of avoiding, as far as possible, the inherent differences in scale between contrasting organisms so that their performances can be compared on an equitable basis

- The **Relative Growth Rate (RGR)** of a plant at an instant in time ( $t$ ) is defined as **the increase of plant material per unit of material present per unit of time**.
  - The equation is written as:  $RGR = \frac{1}{W} \frac{dW}{dt}$  -  $W$  stands for Weight
  - To calculate the RGR curve, we will leverage on the previous modelisation of the Weight curves (i.e. `fitObj` object obtained by the `fitSigmoid` function)

- Then we will apply linear modeling using the 'cv.glmnet' in order to determine which variable(s) could explain the fruit growth.

## Linear Modeling with cv.glmnet

**run\_cvglmnet** :Application of linear modeling using the 'cv.glmnet' function of the R glmnet package

- for the Relative Growth Rate (RGR)
- using the models previously fitted by the fitSigmoid function (fitObj)
- by selecting some one or more data subsets (setNameList - the data subsets will be merged if severals)
- alpha=1 => lasso penalty, alpha=0 => ridge penalty, 0 < alpha < 1 => elastic-net penalty

## GLMNET
