26 **Abstract**

27 *Vibrio cholerae*, the agent of the deadly human disease cholera, propagates as a curved rod-
28 shaped bacterium in warm waters. It is sensitive to cold, but persists in cold waters under the
29 form of viable but non-dividing coccoidal shaped cells. Additionally, *V. cholerae* is able to
30 form non-proliferating spherical cells in response to cell wall damage. It was recently reported
31 that L-arabinose, a component of the hemicellulose and pectin of terrestrial plants, stops the
32 growth of *V. cholerae*. Here, we show that L-arabinose induces the formation of spheroplasts
33 that lose the ability to divide and stop growing in volume over time. However, they remain
34 viable and upon removal of L-arabinose they start expanding in volume, form branched
35 structures and give rise to cells with a normal morphology after a few divisions. We further
36 show that WigKR, a histidine kinase/response regulator pair implicated in the induction of a
37 high expression of cell wall synthetic genes, prevents the lysis of the spheroplasts during
38 growth restart. Finally, we show that the physiological perturbations result from the import
39 and catabolic processing of L-arabinose by the *V. cholerae* homolog of the *E. coli* galactose
40 transport and catabolic system. Taken together, our results suggest that the formation of non-
41 growing spherical cells is a common response of *Vibrios* exposed to detrimental conditions.
42 They also permit to define conditions preventing any physiological perturbation of *V.*
43 *cholerae* when using L-arabinose to induce gene expression from the tightly regulated
44 promoter of the *Escherichia coli* *araBAD* operon.

45 **Importance**

46 *Vibrios* among other bacteria form transient cell wall deficient forms as a response to different
47 stresses and revert to proliferating rods when permissive conditions have been restored. Such
48 cellular forms have been associated to antimicrobial tolerance, chronic infections and
49 environmental dispersion.

50 The effect of L-Ara on *V. cholerae* could provide an easily tractable model to study the ability
51 of *Vibrios* to form viable reversible spheroplasts. Indeed, the quick transition to spheroplasts
52 and reversion to proliferating rods by addition or removal of L-Ara is ideal to understand the
53 genetic program governing this physiological state and the spatial rearrangements of the
54 cellular machineries during cell shape transitions.

55 **Introduction**

56 Cholera is an acute diarrhoeal disease caused by ingestion of food or water contaminated with
57 *Vibrio cholerae*, a curved rod shape bacterium that propagates in warm briny and salty waters.
58 Cold stops *V. cholerae* proliferation. However, the bacterium has the ability to persist for
59 months in cold water under the form of coccoid bodies and return to growth when the sea
60 temperature rises (1–3). Similarly, *V. cholerae* is known to persist under a spherical form in
61 biofilms (4) and to survive exposure to antibiotics inhibiting cell wall synthesis under the
62 form of spheroplasts, i.e. a spherical cell in which the cell wall has been partially or
63 completely removed (5).

64 The high propagation rate of *V. cholerae* and its capacity to survive unfavorable growth
65 conditions have led to several pandemics, which have caused and are still causing major
66 socio-economic perturbations (6). Seven cholera pandemics have been recorded since the
67 beginning of the 18th century. Isolates of the current on-going pandemic, which started over
68 50 years ago, are rapidly drifting (7–11). It is suspected that the constant appearance of new
69 atypical pathogenic variants of *V. cholerae* will eventually lead to a more virulent strain that
70 will start a new pandemic, which motivated extensive research on the physiology of the
71 bacterium and its evolution towards pathogenicity (7–11). The use of a tightly-regulated high-
72 level expression inducible system based on the regulation of the promoter of the *Escherichia*
73 *coli araBAD* operon by the AraC regulator, known as the P_{BAD} system (12), played an
74 instrumental role in many *V. cholerae* studies (13). The AraBAD enzymes allow *E. coli* to

75 exploit L-arabinose (L-Ara), a component of the hemicellulose and pectin of terrestrial plants,
76 as a carbon and energy source (14). AraC acts both as a positive and a negative regulator,
77 repressing P_{BAD} in the absence of L-Ara and activating its transcription when bound to it (14).
78 *V. cholerae* lacks a *bona fide* arabinose import and metabolism pathway. Nevertheless, the
79 *E. coli* P_{BAD} system proved to be very effective in *V. cholerae*, which suggested that L-Ara
80 was imported in the cytoplasm of the cells. However, we and others recently reported that L-
81 Ara could interfere with the growth of *V. cholerae* (15, 16), calling for a better understanding
82 of the impact of L-Ara on the physiology of this bacterium.

83 Here, we show that *V. cholerae* cells stop dividing or elongating and lose their characteristic
84 curved rod cell shape in the presence of >1% (w/v) and >0.1% (w/v) of L-Ara in rich and
85 poor media, respectively. *V. cholerae* cells become spherical and morphologically similar to
86 spheroplasts obtained by exposure to cell wall targeting antibiotics (5) or to coccoid bodies
87 formed in cold temperatures (1, 2, 17). We further found that mutants with impaired
88 physiology are more sensitive to the presence of L-Ara, morphologically transitioning to
89 spheroplasts with as little as 0.01% (w/v) of L-Ara in poor media. We show that the
90 spheroplasts induced by L-Ara are able to revert to exponentially growing rods in only a few
91 generations when L-Ara is removed, demonstrating that they remain viable. Finally, we
92 demonstrate that L-Ara is imported and processed by the *V. cholerae* homologs of the *E. coli*
93 galactose transport and catabolic enzymes and that one of its by-product perturbs the
94 physiology of the cell by entering the glycolysis pathway. Taken together, these results
95 suggest that formation of spherical cells might be a general physiological response of *Vibrios*
96 when faced with detrimental conditions. From a technical point of view, they permit to define
97 conditions that allow the use of the P_{BAD} expression system in *V. cholerae* while preventing
98 any perturbation of the physiological state of the cells.

99

100 **Results**

101 **L-arabinose induces the formation of non-dividing spherical cells**

102 To study the effect of L-Ara on cell morphology and growth, we added increasing
103 concentrations of L-Ara to wild-type N16961 *V. cholerae* in the early exponential phase in
104 different liquid media. Cells grown in M9-MM appeared with a wild-type rod shape in the
105 absence or up to 0.02% (w/v) L-Ara, but >90% of the cells became spherical in few hours in
106 the presence of 0.1% (w/v) L-Ara (Figure 1A). In cultures grown in M9-MM supplemented
107 with casamino acids (CAA), spherical cells started to appear at 0.2% (w/v) of L-Ara, and the
108 majority of the cells became spherical at 0.5% (w/v) of L-Ara. In LB, the concentration of L-
109 Ara had to be increased up to 1% (w/v) to induce morphological changes (Figure 1A). The
110 spherical shape of L-Ara treated cells resembles that of non-proliferative cells obtained by
111 treating *V. cholerae* cells with cell wall targeting antibiotics (5) or by incubating them at 4°C
112 (2, 4), even though at cold temperatures cells appear to be smaller in size (Figure 1B).

113 In parallel to microscopic inspection, we followed the optical density of cell cultures over
114 time. In all tested media, L-Ara had a detrimental effect on cell proliferation at the same
115 concentrations at which it induced the formation of spherical cells (Supplementary Figure 1).
116 Cell growth was inhibited shortly after the addition of L-Ara, at an optical density at which
117 cells would have otherwise kept growing exponentially, indicating that L-Ara induced a rapid
118 metabolic arrest (Supplementary Figure 1).

119 *V. cholerae* is known to be sensitive to high concentrations of several carbon sources,
120 including glucose (18). None of 8 other commonly used carbon sources had similar effects on
121 cell shape and growth, including D-arabinose (Table 1 and Supplementary Figure 2).

122 The L-Ara phenotype was not restricted to N16961, strain isolated in Bangladesh in the
123 1970s, but it was shared among the most prominent pandemic *V. cholerae* serotype O1 El Tor
124 strains such as C6706, isolated in a cholera outbreak in Peru in the 1990s, and E7946, isolated

125 in Bahrain in 1978. A *V. cholerae* non-O1 non-139 was similarly affected by L-Ara exposure
126 (Supplementary Figure 3).

127 **Mutants with impaired physiology are more sensitive to L-Ara**

128 We had previously noticed that it was impossible to use the P_{BAD} system to produce proteins
129 of interest in a few *V. cholerae* mutants because the presence of L-Ara inhibited their growth.
130 The above results prompted us to revisit the phenotype of two of those mutants whose growth
131 was completely arrested by the addition of as little as 0.01% (w/v) of L-Ara in M9-MM: a
132 N16961 strain carrying two copies of the *ssb* gene, which codes for an essential single strand
133 DNA binding protein implicated in the regulation of replication, transcription and
134 homologous recombination repair (19), and a derivative of the MCH1 monochromosomal
135 strain, in which the SImA nucleoid occlusion protein was overproduced (20). In both cases,
136 we observed that 0.01% (w/v) of L-Ara was sufficient to induce the formation of spherical
137 cells in the entire cell population (Figure 1C).

138 **Transition dynamics to spherical cells at the population level**

139 To visually inspect the morphological transition at the population level over time, we
140 collected cell samples every hour for 10 hours after L-Ara addition and examined them at the
141 microscope. Cells were divided in three categories based on their shape: cells with a rod
142 shape, cells composed of a rod and a small or large irregular bulge protruding from the cell
143 wall, which we refer to as bleb, and cells with a spherical shape (Figure 2A). In cell cultures
144 grown at 30°C, spherical cells started to appear after 5 hours and comprised 90% of the cell
145 population after 9 hours. The sharp increase in the proportion of spherical cells in the
146 population corresponded to an equally fast decline in rod shaped cells, which dropped to less
147 than 10% of the cell population at the end of the experiment. Blebbing cells appeared around
148 4 hours after L-Ara addition. Blebs were randomly located on the surface of the cells. In
149 particular, there was no preference for mid-cell or cell pole locations (Supplementary Figure

150 4). Cells with protruding blebs never represented more than 5% of the entire cell population
151 and almost disappeared at the end of the time course, which suggested that they corresponded
152 to a transient state between the rod and the spherical state. We refer to them as transitioning
153 cells. Taken together, these results suggest that a few hours are required after growth arrest
154 before morphological transition. However, once transition is initiated the formation of
155 spherical cells is very fast.

156 In a similar time course experiment performed at 37°C, cells appeared to respond faster to L-
157 Ara: the first blebs appeared 3 hours after L-Ara addition and after 5 hours about 40% of the
158 cell population had completed transition to spherical bodies (Supplementary Figure 5).

159 The size of the spherical cells was heterogeneous and the diameter of the majority of cells
160 was comprised between 1.5 and 1.8 μm (Figure 2B). The average diameter of the spherical
161 cells did not change between the 7, 8, 9 and 10 hour time points after L-Ara addition,
162 suggesting that once formed, spherical cells neither decreased nor increased in volume
163 (Figure 2C). Based on the measured dimensions of spherical and rod-shaped cells, we
164 estimate that the cell volume of spherical cells is around 2.5 times bigger than that of
165 exponentially growing rod cells.

166 **Transition dynamics to spherical cells at the single cell level**

167 We performed time-lapse video-microscopy experiments to inspect the transition process
168 from rod to sphere at the single cell level (Figure 2D and Movie 1). All the observed cells
169 displayed the same transition pattern. After exposure to L-Ara, a single bleb appeared at the
170 bacterial cell surface. As the bleb increased in size, the original cell was assimilated into the
171 forming sphere until the original rod shape was completely lost. The time when a bleb became
172 visible on the cell surface and its location varied from cell to cell. However, once started,
173 completion of the morphological change was comparable in all cells, with the exception of a

174 few rare cells that lysed during the process (Movie 2). On an agarose M9-MM pad, blebbing
175 cells transitioned to spheres in around 2 to 3 hours at 30°C (Figure 2D and Movie 1).

176 **L-Ara induced spherical cells are cell wall deficient**

177 The spherical shape of L-Ara treated cells is similar to cell wall deficient forms that have
178 completely or almost entirely lost the peptidoglycan (PG) layer, which suggested a process of
179 cell wall degradation or PG remodelling mechanism (21). To verify this point, we compared
180 the PG content and composition of *V. cholerae* exponentially growing cells and L-Ara
181 induced non-dividing spherical cells (Table 2). To limit contamination by the PG of cells that
182 had not completely transformed into spheres in the presence of L-Ara, we used MCH1 cells
183 expressing an additional copy of SlmA because they fully transitioned to spherical cells in the
184 presence of as little as 0.01% (w/v) of L-Ara (Figure 1C).

185 The PG of exponentially growing cells and cells that had completely transitioned to spheres
186 after the addition of 0.1% (w/v) of L-Ara was extracted and submitted to UPLC analysis
187 (Supplementary Figure 6A). The area of the UPLC profiles showed that the amount of PG per
188 cell in L-Ara treated bacteria was around 10 times lower than the amount present in rod-
189 shaped cells (Supplementary Figure 6B). In addition, we found that glycan chains were twice
190 shorter in L-Ara treated cells than in untreated cells. The length of glycan chains is calculated
191 based on the number of anhydro-muropeptides (22), which results from the activity of lytic
192 transglycosylases (23, 24). Therefore, the observed reduction in the average glycan chain
193 length suggests an increase of lytic transglycosylase activity in the presence of L-Ara. Finally,
194 we observed that the amount of DAP-DAP cross-linked muropeptides significantly increased
195 in L-Ara treated cells. Taken together, these results indicate that cell wall metabolism is
196 perturbed after L-Ara exposure and that spherical cells are almost completely deprived of the
197 PG layer, which corresponds to the definition of a spheroplast.

198 **L-Ara induced spheroplasts are viable**

199 To evaluate if L-Ara had a detrimental effect on cell viability we estimated the number of
200 viable bacteria in a time course experiment. A culture of N16961 cells was split in two after 2
201 hours of growth and L-Ara was added to one of the two halves. The number of viable cells in
202 each culture was determined by plating aliquots on LB plates and counting the number of
203 colonies. Viable cell count kinetics (represented as colony forming units, CFU) showed that
204 L-Ara addition had an immediate inhibitory effect on cell proliferation but did not cause a
205 corresponding decline in cell viability (Figure 3A). Indeed, 75% of the number of cells before
206 L-Ara addition gave rise to colonies after a 10 hours incubation with L-Ara (Figure 3B).

207 Time-lapse video-microscopy was performed to determine how non-proliferating spherical
208 cells could return to proliferation and recover a curved rod shape after L-Ara removal. Single
209 cell analyses showed that reversion to proliferating rods started with the elongation of the
210 spheroplasts, which was followed by the formation of multiple protrusions on their surface
211 (Figure 3C and Movie 3). The protrusions elongated outward, giving rise to branched cells.
212 Curved rod shape cells were recovered after a few division events. The time required to
213 initiate elongation greatly differed from cell to cell: the recovery process started almost
214 immediately after the removal of L-Ara in some cells but took a few hours to initiate in
215 others. However, the time between the initiation of the recovery process and its completion
216 was similar for all the cells. On an agarose M9-MM pad at 30°C, cells transitioned from
217 elongating spheres to symmetrically dividing rods in around 4 to 5 hours. It was not necessary
218 to add osmo-protectants in liquid or on agarose pads to avoid the lysis of spherical cells
219 before and after the initiation of the proliferation recovery process.

220 Time-lapse video-microscopy observations further suggested that the overall 25% loss of
221 CFU after 10 hours of L-Ara treatment (Figure 3B) was accounted for by the number of cells

222 that lysed during the transition to spheroplasts after the addition of L-Ara (Movie 2) and by
223 those that lysed during the recovery process after L-Ara removal (Movie 4).

224 ***wigKR* is essential for the recovery of cells after L-Ara treatment**

225 The histidine kinase/response regulator pair WigKR (also known as VxrAB) is thought to
226 induce a higher expression of the full set of cell wall synthetic genes in response to cell wall
227 damage (25). It was previously reported that it was essential for the recovery of cell shape and
228 the return to proliferation of *V. cholerae* cells treated with cell wall targeting antibiotics (25),
229 which prompted us to inspect the effect of L-Ara on $\Delta wigKR$ cells. We observed no
230 differences in the growth arrest and formation of spherical cells of the $\Delta wigKR$ strain in the
231 presence of L-Ara (Supplementary Figure 7A). As observed before, spherical cell formation
232 initiated from a single bleb randomly distributed on the surface of the cell. However, $\Delta wigKR$
233 spherical cells immediately started to grow in diameter when L-Ara was removed, expanding
234 continuously in size until they exploded (Figure 3D and Movie 5). On the contrary, $\Delta wigKR$
235 cells that had not yet transitioned to spheroplasts were able to return to a proliferative state
236 without any obvious defect (Movie 6). After a 10 hours incubation with L-Ara, only 10% of
237 the $\Delta wigKR$ cells could still form colonies, which corresponded to the proportion of cells that
238 had not started transitioning to spheres (Supplementary Figure 7B). Taken together, these
239 results suggest that the histidine kinase/response regulator pair WigKR plays an essential role
240 in the recovery of the L-Ara induced spheroplasts.

241 **Identification of genes required for L-Ara sensitivity**

242 In contrast to cell wall targeting antibiotics, growth arrest and spheroplast formation were
243 unlikely to result from the action of L-Ara on the cell surface or in the periplasm of *V.*
244 *cholerae*. *V. cholerae* lacks a *bona fide* arabinose import and metabolization pathway, but the
245 effectiveness of the *E. coli* P_{BAD} promoter regulation by L-Ara suggested that it was at least

246 passively imported in the cytoplasm of this bacterium. To identify putative factors involved in
247 the response of *V. cholerae* cells to L-Ara, we performed two complementary genetic screens.
248 First, we employed a screen based on the enrichment of L-Ara-insensitive mutants in a cell
249 population grown in liquid in M9-MM supplemented with 0.2% (w/v) L-Ara. We constructed
250 a library of N16961 mutants with a Mariner transposon (Tn), which randomly inserts at 5'-
251 TA-3' sites (26). We grew the library in M9-MM supplemented with 0.2% (w/v) L-Ara for 18
252 hours. Aliquots were collected before L-Ara addition and after 9 and 18 hours of incubation
253 with L-Ara. Deep sequencing was used to determine all the positions at which the Tn was
254 inserted in the collected libraries. We thus identified nine genetic loci in which Tn insertions
255 were significantly overrepresented after growth in presence of L-Ara (Figure 4A). The
256 transposition frequency and insertion profile differed in the overrepresented genes (Figure
257 4B). Tn insertions covered both DNA strands of the entire gene length of *vc1325*, *vc1327*,
258 *vc1328*, *vc1595*, *vc1596* and *vc0263*, suggesting that the product of these genes was
259 implicated in the physiological effect of L-Ara. Tn insertions covered the entire length of a
260 specific DNA strand of *vc0262*, suggesting that they had a polar effect on the expression of
261 *vc0263*. The overrepresentation of Tn insertions was restricted to only one of the multiple 5'-
262 TA-3' sites present in the entire gene length of *vc0779* and *vc2621*, suggesting that L-Ara
263 insensitive phenotype could be provided by an additional suppressor mutation located at
264 another genetic locus. The suppressor capacity of the inactivation of *vc1325*, *vc1327*, *vc1328*,
265 *vc1595*, *vc1596* and *vc0263* was confirmed by using the corresponding mutants in an ordered
266 mapped Tn library of the wild-type C6706 strain (27). Inactivation of *vc1325*, *vc1327*,
267 *vc1328*, *vc1595*, *vc1596* and *vc0263* fully restored growth of C6706 in presence of L-Ara
268 (Supplementary Figure 8).

269 In addition, as L-Ara insensitive mutants presenting a growth defect cannot be identified with
270 a screen based on growth enrichment, we decided to directly plate a random Tn insertion

271 library on M9-MM plates containing L-Ara. To limit the number of false positives, i.e. the
272 formation of colonies by cells still sensitive to L-Ara, we used the MCH1 strain carrying an
273 additional copy of the *slmA* gene, which fully transitions to spheres in the presence of as little
274 as 0.01% (w/v) of L-Ara (Figure 1C). Plating of the Tn insertion library on M9-MM plates
275 containing 0.1% (w/v) L-Ara resulted in the formation of 11 colonies, 9 of which were
276 confirmed to be L-Ara insensitive after re-isolation on fresh L-Ara plates. Sequencing showed
277 that they corresponded to Tn insertions in six different genes (Table 3 and Supplementary
278 Figure 9), five of which had already been detected in the growth enrichment screen (*vc1325*,
279 *vc1327*, *vc1328*, *vc1596* and *vc0263*). In addition, three independent Tn hits were obtained in
280 *vc2689*. The strain corresponding to the inactivation of *vc2689* was missing in the ordered
281 mapped Tn library of the wild-type *V. cholerae* C6706 strain (27). Therefore, we directly
282 engineered the mutation in the N16961 wild-type background to confirm that its inactivation
283 suppressed the effect of L-Ara (Supplementary Figure 8). L-Ara reduced the growth rate of
284 *vc2689* mutants (Supplementary Figure 8). However, microscopic inspection revealed a
285 majority of rod-shaped cells and a few isolated spherical cells, suggesting that L-Ara
286 sensitivity was reduced even though not completely suppressed.

287 Discussion

288 It was recently reported that L-Ara inhibited the proliferation of *V. cholerae* (15, 16). Here,
289 we show that it is associated with a change in the morphology of the cells from a curved rod
290 shape to a spherical form (Figure 1). The spherical cells lose the ability to divide and stop
291 growing in volume over time, suggesting a major metabolic arrest (Figure 2). We found that
292 L-Ara induced spherical cells are spheroplasts, i.e. they have almost completely lost their cell
293 wall (Table 2 and Supplementary Figure 6). Nevertheless, they remain viable and once L-Ara
294 is removed from the environment they resume proliferation and revert to the original cell
295 shape after a few divisions (Figure 3).

296 **Metabolism arrest is linked to the processing of L-Ara by the galactose pathway**

297 We found that the addition of L-Ara almost immediately stopped *V. cholerae* proliferation in
298 both fast and slow growing conditions, in contrast to the addition of 8 other commonly used
299 carbon sources (Figure 1 and Table 1). *V. cholerae* lacks a *bona fide* L-Ara import and
300 degradation pathway. However, the effectiveness of the regulation of the *E. coli* P_{BAD}
301 promoter in *V. cholerae* suggested that it was at least passively imported in the cytoplasm of
302 the bacterium, where it interfered with the metabolism. We performed 2 genetic screens to
303 determine which cellular processes might be involved in the action of L-Ara.

304 We identified 7 genes whose inactivation suppressed the sensitivity to L-Ara (Figure 4 and
305 Table 3). 6 of those genes can be directly (*vc1325*, *vc1327*, *vc1328*, *vc1596* and *vc1596*) or
306 indirectly (*vc0263*) linked to the galactose Leloir catabolic pathway. *vc1325*, *vc1327* and
307 *vc1328* code for homologues of the 3 components of the *E. coli* ABC galactose transport
308 system, the periplasmic binding protein MglB, the ATP-binding protein MglA and the
309 integral membrane permease MglC, respectively (28, 29). *vc1595* codes for a homologue of
310 the *E. coli* galactokinase GalK, the first enzyme in the Leloir pathway of galactose
311 metabolism (30). *vc1596* codes for a homologue of *E. coli* GalT, the galactose 1-phosphate
312 uridylyltransferase. *vc0263* codes for a putative homologue of the enzyme initiating colanic
313 acid synthesis in *E. coli*, WcaJ (31), which was also described to act as a galactose-1-
314 phosphate transferase *in vitro* (32). These results suggest that L-Ara is imported in the
315 cytoplasm of *V. cholerae* by the galactose transporter and processed by the galactose catabolic
316 enzymes (Figure 5). In *Sinorhizobium meliloti*, the arabinose transporter AraABC has been
317 described to play a role in galactose uptake (33), suggesting a similarity in the activity of the
318 arabinose and galactose transporter.

319 Finally, the 7th suppressor gene we identified, *vc2689*, codes for a homologue of the *E. coli* 6-
320 phosphofructokinase PfkA, a key enzyme in the glycolysis pathway (34) (Figure 5).

321 Taken together, these results suggest that L-Ara arrests the metabolism of *V. cholerae* because
322 it is mistakenly recognized as a substrate of the Leloir metabolic pathway and that through a
323 series of enzymatic reactions it is converted into a phosphorylated sugar by-product that
324 cannot be further metabolized (Figure 5). Likewise, several studies previously suggested that
325 accumulation of a phosphate ester metabolite could perturb growth: L-Ara inhibits the growth
326 of *E. coli araD* mutants because of the accumulation of L-ribulose 5-phosphate (35);
327 Galactose inhibits the growth of *E. coli galT* mutants because of the accumulation of
328 galactose 1-phosphate (36, 37); Rhamnose stops the growth of *Salmonella* Typhi strains
329 defective in the rhamnose degradation pathway because of the accumulation of L-rhamnulose
330 1-phosphate (35, 38).

331 **L-Ara mediated metabolic perturbation does not prevent the use of P_{BAD}**

332 Importantly, the realization that L-Ara can perturb the metabolism of *V. cholerae* does not
333 jeopardize previous results obtained with the *E. coli* P_{BAD} expression system in this bacterium
334 since L-Ara concentrations lower than those that promote growth arrest and spheroplasts
335 formation are almost always used (Figure 1). However, our study indicates that special care
336 should be taken in future works when using the *E. coli* P_{BAD} expression system in mutants of
337 *V. cholerae* (Figure 1). It also shows how metabolic artefacts linked to L-Ara can be avoided
338 by performing experiments in cells that can import L-Ara but are insensitive to it by mutation
339 of *vc1595*, which codes for the first enzyme probably processing L-Ara in the cytoplasm
340 (Figure 4 and 5).

341 **Spheroplasts formation results from an imbalance in cell wall degradation and synthesis**

342 The analysis of the muropeptide composition of L-Ara treated *V. cholerae* cells showed that
343 they still maintained a residual amount of PG whose structure was remarkably similar to that
344 described for *E. coli* cefsulodin-induced L-forms (39). The dramatic decrease in the average
345 chain-length and corresponding increase in anhydro-muropeptides hint to a higher activity of

346 lytic transglycosylases in cleaving the PG and producing shorter chains. The increase in DAP-
347 DAP cross-linkage, an unusual kind of cross-linkage specifically generated by L,D-
348 transpeptidases (40), further suggests that the metabolic arrest induced by L-Ara affects PBPs
349 activity and stimulates transpeptidation mediated by the L,D-transpeptidase LdtA (41). Taken
350 together, these results suggest that L-Ara promotes the formation of spheroplasts because it
351 induces a metabolic arrest that leads to an imbalance between PG synthesis and degradation.
352 Interestingly, one of the suppressors we identified in the Tn screenings (*vc2689*) codes for a
353 homologue of the glycolytic enzyme PfkA, whose normal metabolic substrate, phosphor-
354 sugar fructose 6-phosphate, is an essential precursor for UDP-GlcNAc and subsequently
355 Lipid II and PG synthesis through the GlmS pathway (42) (Figure 5). It suggests that the
356 imbalance between PG synthesis and degradation might result from the depletion or
357 replacement of phosphor-sugar fructose 6-phosphate by a by-product of L-Ara and/or by the
358 poisoning of GlmS.

359 **WigKR dependent up-regulation of cell wall synthesis genes is essential for recovery**

360 Like L-Ara, antibiotics inhibiting cell wall synthesis promote the formation of viable
361 spheroplasts that can revert to the original cell shape after a few divisions when the antibiotics
362 are removed (5). However, in contrast to L-Ara induced spheroplasts, *V. cholerae* cells
363 exposed to antibiotics inhibiting cell wall synthesis grow in volume over time, suggesting that
364 they are not dormant (Figure 3, (43, 44)). In this regard, antibiotic treated cells are more
365 similar to bacterial L-forms, which can be obtained in osmotic stabilizing media in several
366 microorganisms, including *E. coli*, by treating cells with lysozyme (45), by adding the β -
367 lactam cefsulodin (a specific inhibitor of the penicillin binding proteins PBP1A and PBP1B)
368 (39, 46), or by inhibiting synthesis of the Lipid II cell wall precursor with fosfomycin (47).
369 The spheroplasts induced by the treatment of Δ *wigKR* cells by L-Ara increased in volume
370 when L-Ara was removed from the growth media, demonstrating that cell metabolism was

371 very rapidly restored (Figure 3D). However, the expansion in volume of the cells led to lysis
372 (Figure 3D). These results indicate that the recovery of a constitutive level of PG synthesis
373 was not sufficient to expand the residual amount of cell wall left in the spheroplasts to
374 accommodate the increase in cellular material, as observed for the spheroplasts induced by
375 cell wall targeting antibiotics. These results fit with the idea that the histidine kinase/response
376 regulator pair WigKR dependent up-regulation of the full set of cell wall synthetic genes is
377 necessary for cell shape recovery of *V. cholerae* spheroplasts (25).

378 **L-Ara sensitivity is a common feature of *Vibrios***

379 L-Ara induced spheroplasts formation and inhibition of cell growth is observed in clinically
380 relevant O1 and O139 strains as well as in environmental non-O1 non-O139 strains
381 (Supplementary Figure 3 and (15)).

382 Interestingly, it was shown that L-Ara induced biofilm formation and had an inhibitory effect
383 on cell growth in *Vibrio fischeri* (48). No remarks were made about cell morphology.
384 However, mutations in GalK or the galactose transporter were found to suppress the
385 phenomenon, as observed for the action of L-Ara in *V. cholerae* (48). Thus, L-Ara sensitivity
386 could be a phenotype shared by different species of *Vibrios*.

387 **Methods**

388 **Plasmids and strains**

389 Bacterial strains and plasmids used in this study are listed in Table 4. Strains were rendered
390 competent by the insertion of *hapR* by specific transposition and constructed by natural
391 transformation. Engineered strains were confirmed by PCR. Primers are listed in
392 Supplementary Table 1.

393 **Growth curves**

394 If not otherwise indicated, cells were grown at 30°C in M9 minimal medium supplemented
395 with 0.2% (w/v) fructose and 1 µg/ml thiamine (M9-MM), M9-MM + 0.1% casamino acids

396 (M9-MM + CAA) and Luria-Bertani broth (LB) in a 96-well microtiter plate and the optical
397 density at 600 nm followed over time in a Tecan plate reader. The growth curves plotted are
398 the average of three replicates; the standard deviation is represented for each time point. For
399 CFU and rod to sphere kinetics, cells were grown in flasks in M9-MM at 30°C and 37°C,
400 0.2% (w/v) L-Ara was added when indicated. Samples were taken every hour for plating
401 and/or microscopic inspection. Three replicates were performed for each experiment. L-Ara
402 was added to cell cultures with an OD_{600} comprised between 0.02 and 0.05.

403 **L-Ara survival assay**

404 Over-night wild-type (EPV50) and $\Delta wigKR$ (EGV515) cultures were diluted 200 times in
405 M9-MM, followed by 2 hours of growth at 30°C before 0.2% (w/v) L-Ara was added. Cells
406 were checked for transition to spherical morphology at the microscope. Serial dilutions of T_0
407 (before L-Ara addition) and T_{10} (after L-Ara treatment) samples were plated on LB plates and
408 the number of colonies used to calculate the CFU at T_0 and T_{10} . The ratio $CFU_{T_{10}} / CFU_{T_0}$
409 is used to calculate the percentage of cells able to survive L-Ara treatment and revert to
410 proliferation.

411 **Microscopy**

412 Cells were spread on a 1% (w/v) agar pad (ultrapure agarose, Invitrogen) for analysis. For
413 snapshots, images were acquired using a DM6000-B (Leica) microscope. For time-lapse
414 analyses the agarose pad was made using M9-MM with 0.2% (w/v) L-Ara if needed and
415 images were acquired using an Evolve 512 EMCCD camera (Roper Scientific) attached to an
416 Axio Observe spinning disk (Zeiss). To observe rod to sphere transition on agarose pads,
417 0.2% (w/v) L-Ara was added in liquid M9-MM cultures 2 hours before transferring cells on
418 agarose pads containing L-Ara and starting microscopic imaging.

419 **Transposon insertion deep sequencing-based screen**

420 The Tn library was constructed in an EPV50 background and libraries for Illumina
421 sequencing were prepared as described in Espinosa *et al.* (49). Aliquots of the transposon
422 library were thawed on ice and $\sim 10^9$ cells were diluted into 100 ml of M9-MM and grown for
423 1 hour at 30°C before adding 0.2% (w/v) L-Ara. The culture was incubated at 30°C in a
424 shacking incubator for additional 18 hours. Samples for library construction and deep
425 sequencing were collected before L-Ara addition and after 9 and 18 hours of incubation with
426 L-Ara.

427 **Tn-seq analysis**

428 Cutadapt was used to remove adapters and transposon sequences. Genome sequences were
429 mapped using bwa as described in (50, 51). Transposon insertions were visualized using the
430 Artemis browser (52).

431 **Transposon mutagenesis screen on plate**

432 The transposon mutagenesis was performed conjugating the *E. coli* strain SM10 λ
433 *pir*/pSC189, which carries a mini-Himar transposon associated to a kanamycin resistance,
434 with the *V. cholerae* strain EGV299. In detail, 1 ml of culture of EGV299 grown to OD₆₀₀ 0.3
435 was mixed with 100 μ l of donor strain SM10 λ *pir* carrying the transposon donor plasmid
436 pSC189 grown to OD₆₀₀ 0.5. Each mixture was pelleted, resuspended and deposited onto a
437 0.45 μ m filter (Millipore) on a LB agar plate supplemented with DAP. Conjugation was
438 carried out for 6 hours at 37°C and then cells were pooled together and plated directly on M9-
439 MM plates containing kanamycin and 0.1% (w/v) L-Ara and incubated over night at 30°C.
440 Eight conjugations were performed per each library. We constructed two Tn libraries of
441 approximately 300,000 clones each. Mutants able to grow on plate were isolated and
442 inspected at the microscope for growth and morphology in presence of L-Ara. An arbitrary
443 PCR followed by DNA sequencing was performed to determine the Tn insertion site.

444 **Peptidoglycan analysis**

445 EGV217 over-night cultures were diluted 200 times in M9-MM and grown at 30°C. 100 ml
446 were centrifuged after 7 hours of growth and 1 L of culture, to which 0.2% (w/v) L-Ara was
447 added after 2 hours, was harvested after further 7 hours of incubation. Cells were checked for
448 complete transition to spherical morphology at the microscope before harvesting. Previously
449 described methods were followed for muropeptide isolation and ultra-performance liquid
450 chromatography (UPLC) analysis (53, 54). After boiling for 2 hours cell pellets with SDS
451 (sodium dodecyl sulfate), the lysates were left stirring over night at room temperature. Cell
452 wall material was pelleted, washed with MQ water to remove the SDS, and digested with
453 pronase E to remove Braun's lipoprotein. Purified peptidoglycan was re-suspended in MQ
454 water and treated over night with muramidase at 37°C. Soluble muropeptides were reduced
455 with sodium borohydride and the pH then adjusted to 3.5 with phosphoric acid. Samples were
456 injected in an UPLC system to obtain the muropeptide profiles. UPLC separation was
457 performed on a Waters UPLC system equipped with an ACQUITY UPLC BEH C18 Column,
458 130 Å, 1.7 µm, 2.1 mm × 150 mm (Waters) and a dual wavelength absorbance detector using
459 a linear gradient from buffer A (phosphate buffer 50 mM, pH 4.35) to buffer B (phosphate
460 buffer 50 mM, pH 4.95, methanol 15% (v/v)) in a 28-min run with a 0.25 ml/min flow.
461 Elution of muropeptides was detected at 204 nm. Identity of the peaks was assigned by
462 comparison of the retention times and profiles to other chromatograms in which mass
463 spectrometry data have been collected. The relative amounts of the muropeptides and the
464 percentage of cross-linkage were calculated as described by Glauner *et al.* (22). To estimate
465 the amount of peptidoglycan per cell, the total area of the chromatogram was normalized to
466 the OD of the culture. All values are the means of three independent experiments.

467 **Figures and Tables Legends**

468 **Figure 1. L-Ara induces loss of rod shape. A.** Phase contrast images of *V. cholerae* N16961
469 cells (strain EPV50) grown at 30°C in the indicated media with increasing concentrations of
470 L-Ara. **B.** Phase contrast images of *V. cholerae* N16961 cells (strain EPV50) incubated in
471 M9-MM at 4°C for 6 weeks (left panel) and grown in LB with 100 µM Ampicillin (Amp) at
472 30°C (right panel). **C.** Phase contrast images of *V. cholerae* strain EGV299 (MCH1
473 P_{BAD}::*YGFP-slmA*) and EGV300 (N16961 P_{BAD}::*ssb-YGFP*) cells grown in M9-MM at 30°C
474 in presence of 0.01% (w/v) L-Ara. Scale bars = 2 µm.

475 **Figure 2. Transition dynamics to spherical cells.** Cells of *V. cholerae* strain EPV50 were
476 grown in M9-MM at 30°C. L-Ara was added at a concentration of 0.2% (w/v) when
477 indicated. **A.** Kinetics of *V. cholerae* morphological change from rods to spherical cells. Cell
478 shape was inspected at the microscope every hour after L-Ara addition. A representative
479 image for each cell category (rod, transitioning, spherical) is represented. Mean of three
480 independent replicates and the standard deviation are represented. **B.** Diameter distribution of
481 *V. cholerae* spherical cells treated with L-Ara for 10 hours. **C.** Average diameter of *V.*
482 *cholerae* spherical cells over time. Mean of three independent replicates and the standard
483 deviation are represented. **D.** Transition from rods to spherical forms. EPV50 cells were
484 mounted on a M9-MM agarose pad containing 0.2% (w/v) L-Ara. Bright-field still images
485 from time-lapse microscopy experiments. Images were taken every 5 minutes for 12.5 hours.
486 Scale bars = 2 µm.

487 **Figure 3. Recovery of growth and rod shape.** Cells were grown in M9-MM at 30°C. L-Ara
488 was added at a concentration of 0.2% (w/v) when indicated. Viable colony count (CFU) of *V.*
489 *cholerae* cells (strain EPV50) grown with and without L-Ara over time (**A**) and after 10 hours
490 (**B**). Mean of three independent replicates and the standard deviation are represented. In the
491 time-lapse experiments, cells were grown in M9-MM + 0.2% (w/v) L-Ara until they became

492 spherical and then mounted on a M9-MM agarose pad in the absence of L-Ara. Bright-field
493 still images were taken every 5 minutes for 14 hours. **C.** N16961 cells (strain EPV50) rod
494 shape recovery. **D.** Spherical $\Delta wigKR$ cells (strain EGV515) are not able to recover rod shape.
495 Scale bars = 2 μ m.

496 **Figure 4. Transposon insertion mutants insensitive to L-Ara-induced cell growth arrest.**

497 Tn-seq profile of a transposon insertion library in an EPV50 background before (top panel)
498 and after incubation with 0.2% (w/v) L-Ara (middle panel for 9 hours and bottom panel for 18
499 hours). Transposon insertion profile of chromosome 1 is shown in (A). Chromosomal
500 positions are indicated below. Regions with overrepresented transposon insertions in the
501 presence of L-Ara are shown at the bottom and zoomed in (B). Transposon insertion in
502 forward and reverse orientation are indicated by orange and blue vertical lines, respectively.

503 **Figure 5. L-Ara insensitive mutants.** Schematic representation of the galactose and
504 glycolytic metabolic pathways. In red are the genes identified in the Tn screens. The number
505 of Tn insertion (hits) obtained in the screen on plate are specified in between parentheses.
506 Depletion or replacement of D-fructose 6-phosphate by a by-product of L-Ara and/or by the
507 poisoning of GlmS could affect Lipid II synthesis (in blue) and originate cell wall deficient
508 cells.

509 **Table 1.** Carbon sources tested for N16961 (strain EPV50) rod shape loss. They were added
510 to M9-MM at a concentration of 0.2% (w/v), with the exception of glycerol at 10 % (v/v).

511 **Table 2.** Quantification of muropeptides, peptidoglycan cross-linking levels and average
512 chain length of L-Ara treated and non-treated *V. cholerae* cells (strain EGV217). Values are
513 the means of three independent experiments and the standard deviation is represented. *:
514 $p < 0.05$ (t-test with a Two-tailed distribution).

515 **Table 3.** Suppressor mutants of L-Ara induced growth arrest identified in a Tn-based screen
516 on plate. The screening was performed in *V. cholerae* strain EGV299.

517 **Table 4.** List of bacterial strains and plasmids used in this study.

518 **Data Availability**

519 Tn-seq data are available in the ArrayExpress database (<https://www.ebi.ac.uk/arrayexpress>)
520 under accession number E-MTAB-9747.

521 **Acknowledgements**

522 We would like to acknowledge financial support from the Agence Nationale pour la
523 Recherche [ANR19-CE35-0013-01 SurVi]. We thank C. Possoz for helpful discussions and
524 Y. Yamaichi for providing the ordered *V. cholerae* mapped Tn library. Research in the Cava
525 laboratory is supported by the Laboratory of Molecular Infection Medicine Sweden (MIMS),
526 the Swedish Research Council (VR), the Knut and Alice Wallenberg Foundation (KAW) and
527 the Kempe Foundation. S.B.H. was supported by a Martin Escudero Postdoctoral fellowship.

D-galactose ABC transporter: VC1325 (1 hit), VC1327 (1 hit), VC1328 (1 hit)

Tables

Table 1.

Carbon source	Growth	Spherical cells
D-Arabinose	+	-
L-Arabinose	-	+
L-Rhamnose	+	-
D-Glucose	+	-
D-Galactose	+	-
Glycerol	+	-
D-Sucrose	+	-
D-Xylose	+	-
Succinate	+	-

Table 2.

Muropeptide group	Non-treated	L-Ara-treated
*Monomers (%)	48.1 (\pm 0.6)	40.2 (\pm 3.2)
Dimers (%)	43.1 (\pm 1.9)	47.2 (\pm 3.1)
Trimers (%)	8.8 (\pm 2.5)	12.6 (\pm 4.8)
*Anhydro-muropeptides (%)	14.8 (\pm 2.3)	21.9 (\pm 3.7)
*DAP-DAP cross-linked muropeptides (%)	4.9 (\pm 0.7)	7.5 (\pm 0.9)
Peptidoglycan feature	Non-treated	L-Ara-treated
*Total cross-linkage (%)	37.7 (\pm 1.4)	47.2 (\pm 5.0)
*Average glycan chain length	11.7 (\pm 1.4)	7.5 (\pm 1.1)

Table 3.

Gene	Putative function	N. hits
<i>vc0263</i>	Galactosyl-transferase	2
<i>vc1325</i>	Galactoside ABC transporter, periplasmic D-galactose/D-glucose binding protein	1
<i>vc1327</i>	Galactoside ABC transporter, ATP-binding protein	1
<i>vc1328</i>	Galactoside ABC transporter, permease protein	1
<i>vc1595</i>	Galactokinase	1
<i>vc2689</i>	6-Phosphofructokinase, isozyme I	3

Table 4.
