## 1 - Introduction

- Aluminum nanoparticles react with water and produces hydrogen.
- As hydrogen is envisaged as an alternative energy vector, is it possible to consider Ultrafine Aluminum Powder (UFP) as a *in situ* hydrogen source ?

## 3 - Experimental setup

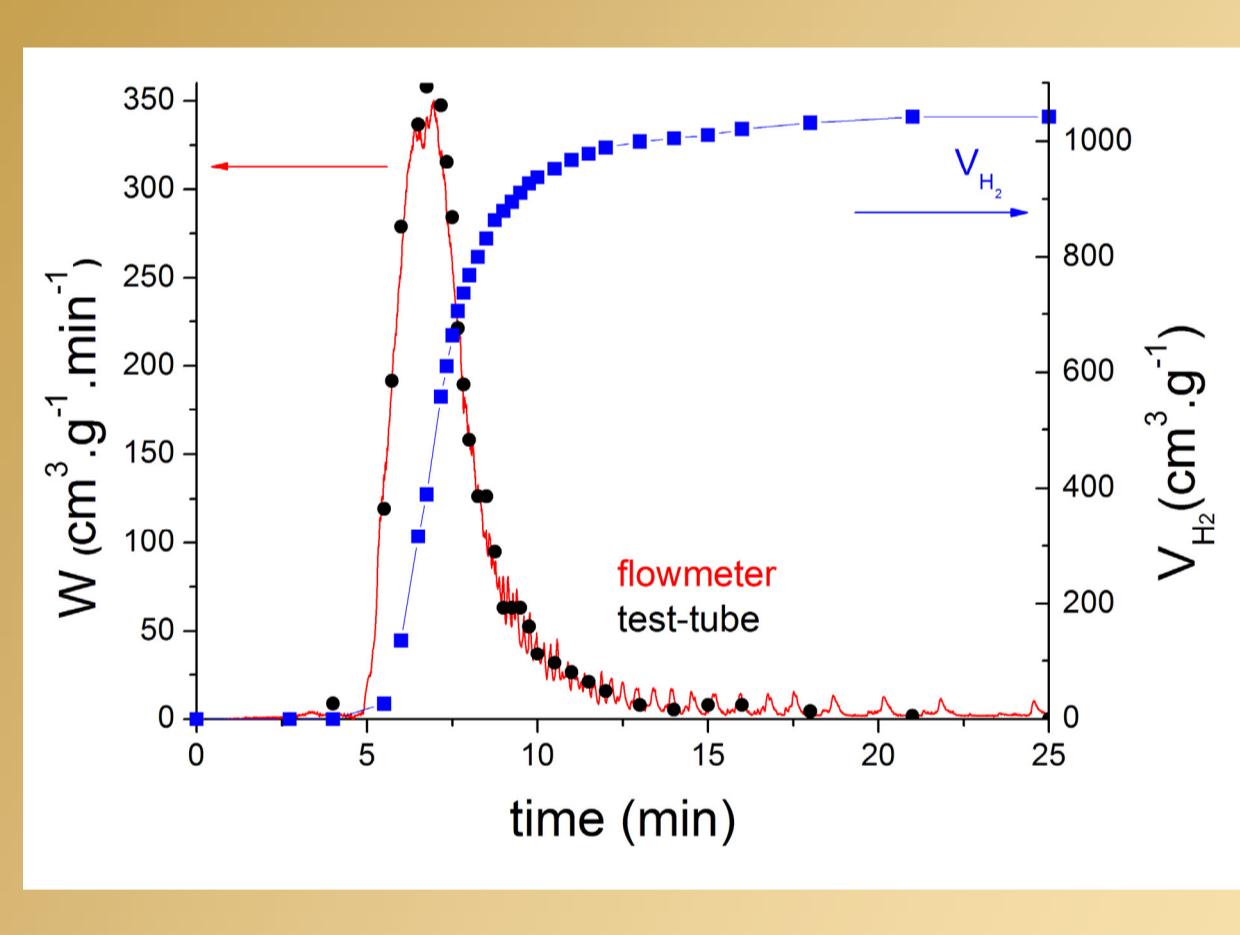

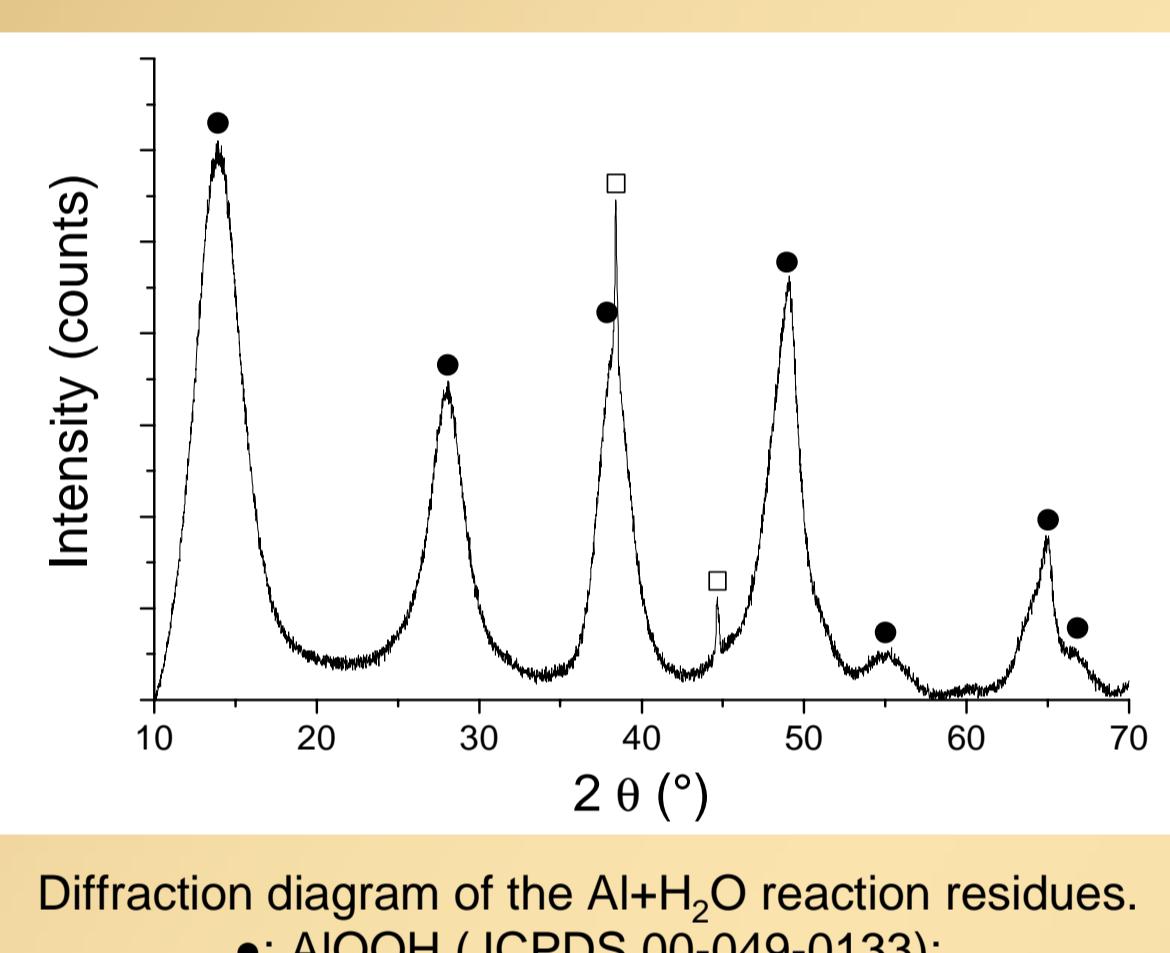

## 2 - Objectives of the present work

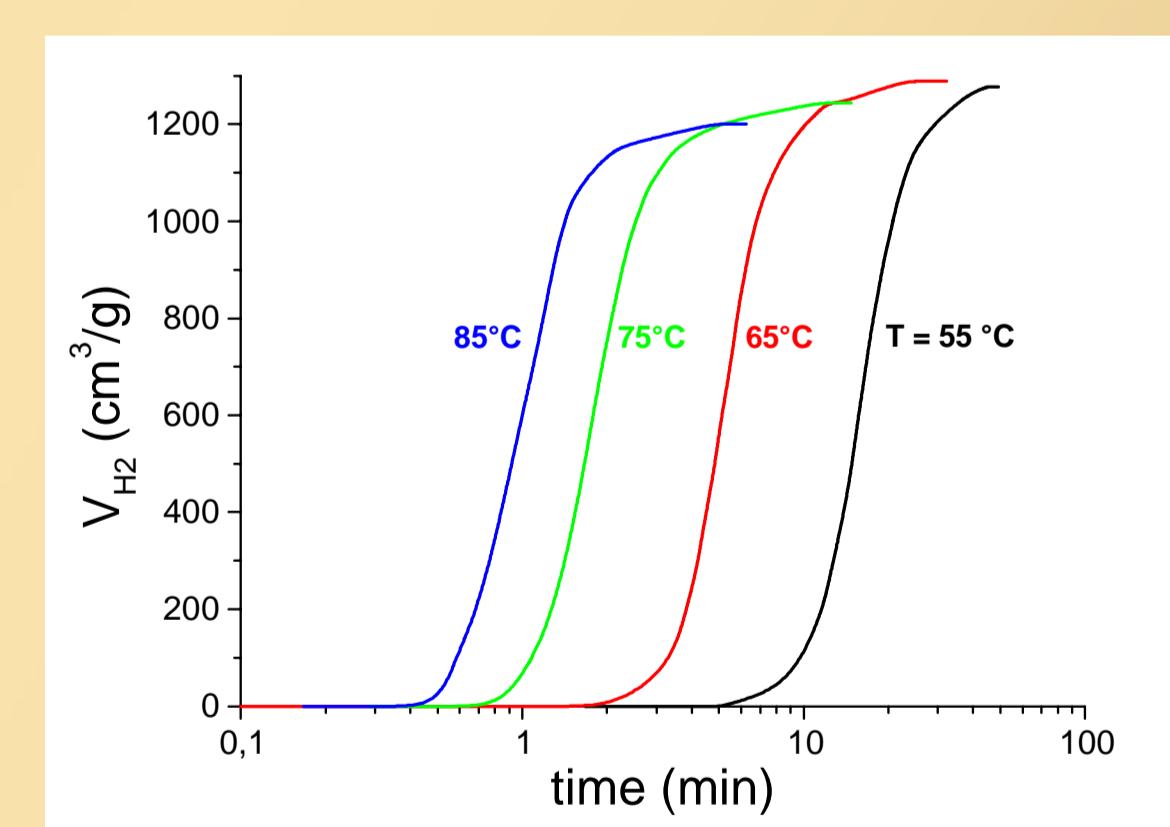

- Understanding of the macrokinetics of the hydroxidation of aluminum.
- Measurements of the H<sub>2</sub> gas release rate as a function of time and temperature.
- Investigating the effect of salt water compared to pure water.

## 4 - Results

- X-ray analyses of the solid reaction residues reveal aluminum oxyhydroxide AlOOH (boehmite)
- Gas-phase chromatography confirms the production of gas dihydrogen (H<sub>2</sub>)
- Al(s) + 2 H<sub>2</sub>O(l) → Al(OH)<sub>3</sub>(s) + 3/2 H<sub>2</sub>(g)

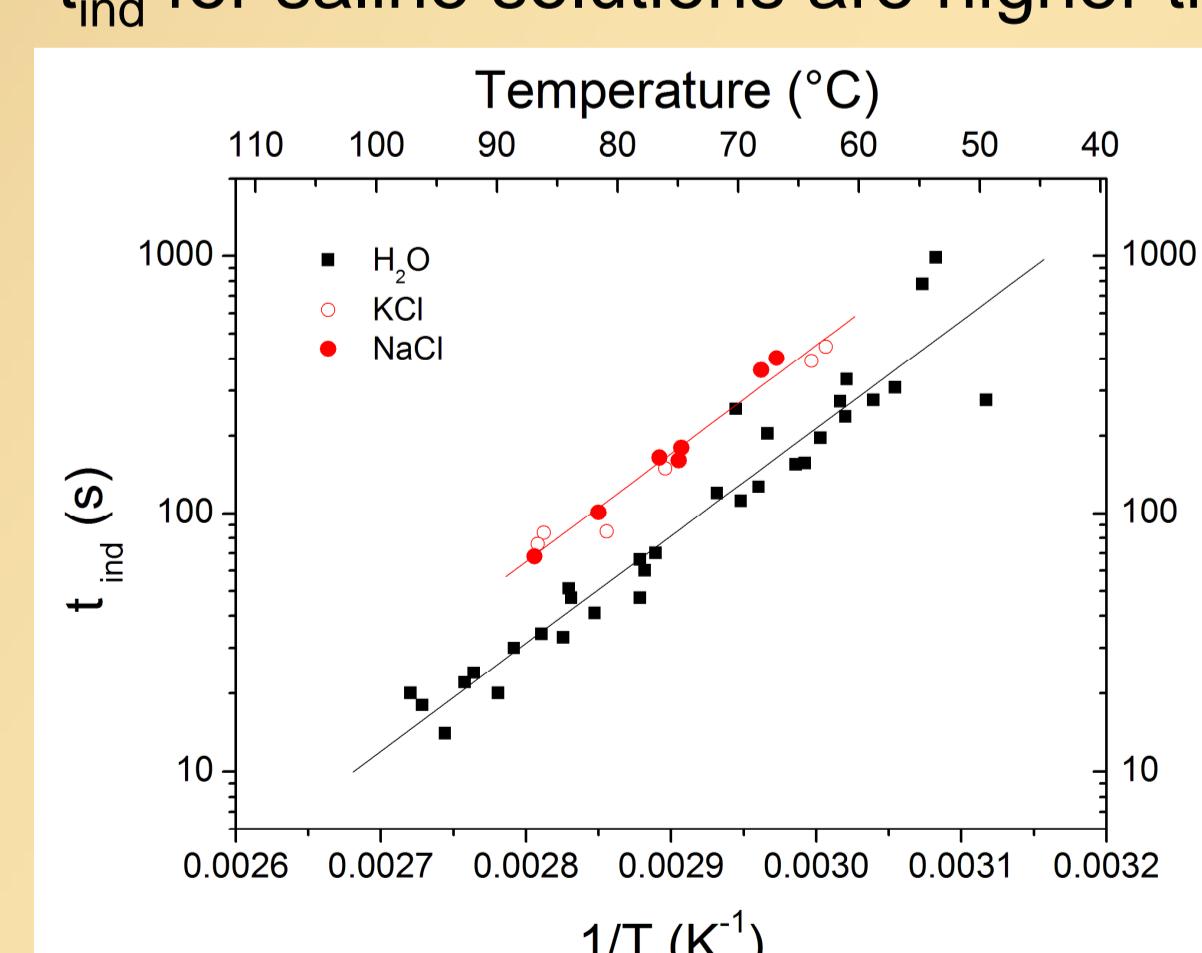

- Reaction starts after an induction period (*t*<sub>ind</sub>)
- After this period, instantaneous H<sub>2</sub> flow rate increases rapidly, exhibits a maximum then decreases.
- S-shaped gas evolution for the total volume of hydrogen observed.

- Temperature dependence of the induction period.
- Rat'ko et al [2] suggest that this induction period corresponds to the hydration of the natural oxide film (Al<sub>2</sub>O<sub>3</sub>).
- The theoretical value of maximum gas release (1350 cm<sup>3</sup> H<sub>2</sub>/g Al) is not reached, but conversion is quasi-complete.

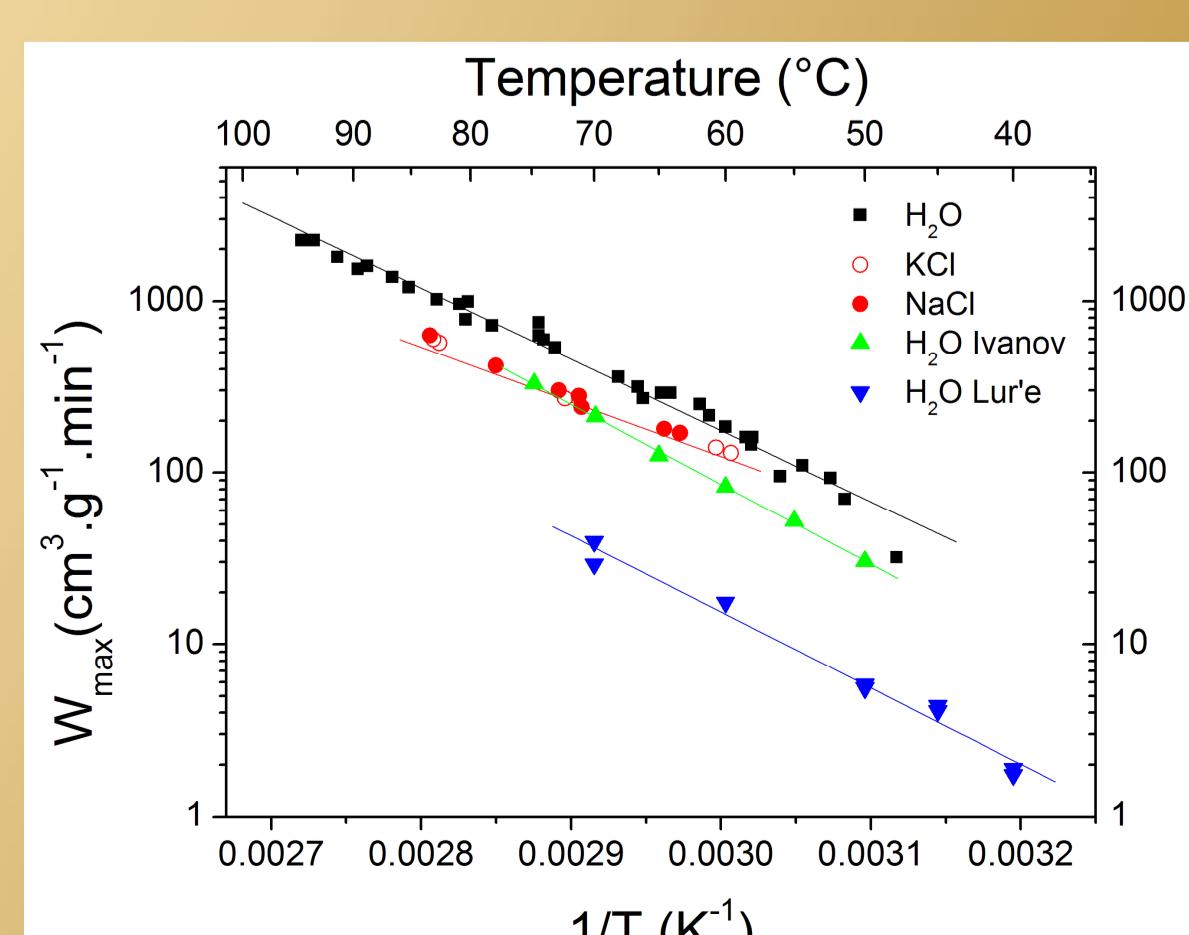

- Induction time and maximal flow rate follow an Arrhenius law.
- t*<sub>ind</sub> for saline solutions are higher than for pure water, with lower W<sub>max</sub>.

$$t_{\text{ind}} = t_{\text{ind}}^{\infty} \cdot \exp\left(\frac{-E_a}{RT}\right)$$

Solution	t <sub>ind</sub> <sup>∞</sup> (s)	E <sub>a</sub> (kJ/mol)
H <sub>2</sub> O	6.41 10 <sup>-11</sup>	-79.9 ± 4.1
NaCl, KCl solutions	1.12 10 <sup>-10</sup>	-80.4 ± 4.3

Solution	W <sub>max</sub> (cm <sup>3</sup> /g/min)	E <sub>a</sub> (kJ/mol)
H <sub>2</sub> O, present work	1.90 10 <sup>-14</sup>	77 ± 1.5
H <sub>2</sub> O, Ivanov <i>et al.</i> [1]	7.93 10 <sup>-15</sup>	89 ± 1.5
H <sub>2</sub> O, Lur'e <i>et al.</i> [3]	3.02 10 <sup>-14</sup>	85 ± 4.3
NaCl, KCl solutions, present work	7.70 10 <sup>-11</sup>	62 ± 3.5

## Operating Conditions

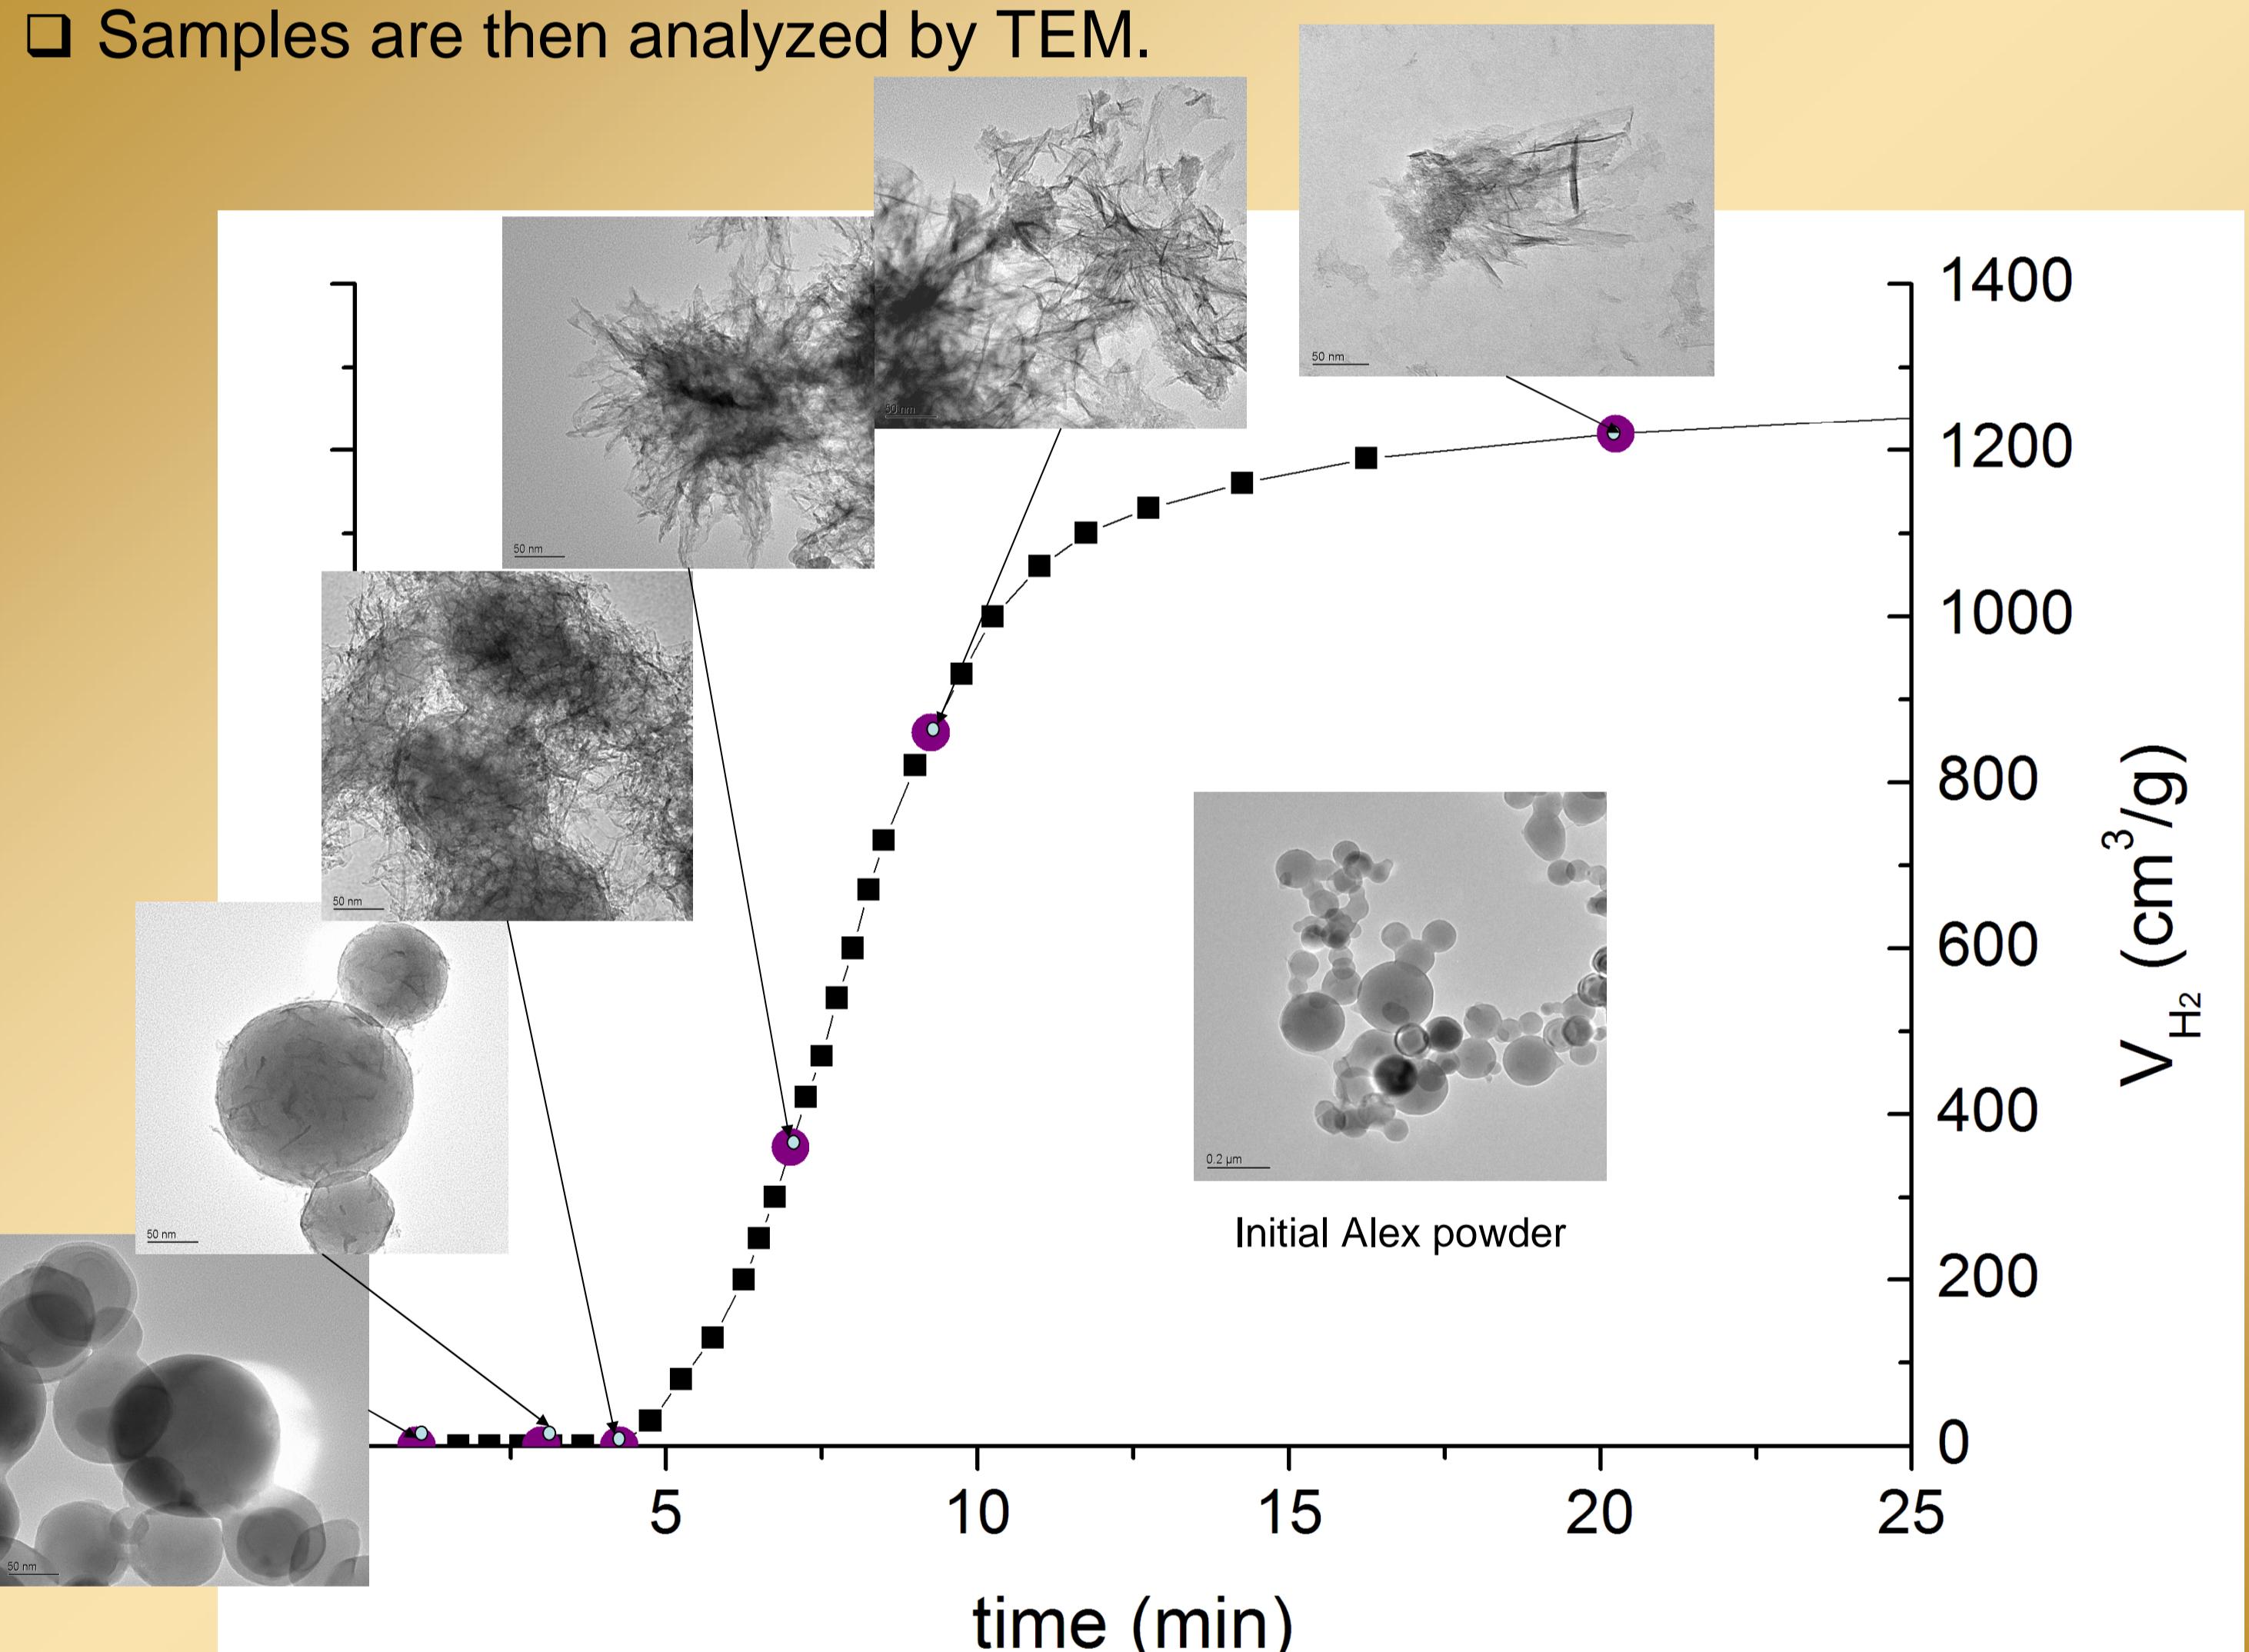

- Isothermal conditions during experiment
- Temperature parameter range [45 – 90 °C]
- Alex powder, air passivated (100 nm mean diameter)
- Mixture composition fixed as:
  - 60 g distilled water
  - 0.1 g of Alex powder
- Saline solution 3% w. (KCl or NaCl)

## Experimental Techniques

- Temperature ⇒ Thermocouple
- H<sub>2</sub> gas release ⇒  $\begin{cases} \text{graduated test-tube} \\ \text{Mass flowmeter} \end{cases}$
- Transmission electron microscopy
- X-ray diffraction

## 5 - TEM Analysis

- Quenching of the reaction by freezing mixture samples at different times.
- Samples are then analyzed by TEM.

## 6 - Conclusions

- The temperature dependence and the influence of salinity have been investigated on the low temperature reactivity of aluminum nanoparticles with water .
- The production of hydrogen is preceded by an induction period corresponding to the hydration-dissolution-precipitation of the oxide film initially covering the particles.
- This induction period is thermally activated (E<sub>a</sub>= -80 kJ/mol).
- The hydrogen released by the reaction (hydroxidation) is characterized by W<sub>max</sub>, which is also thermally activated with similar values of E<sub>a</sub> found in the literature.
- The hydroxidation of the nanopowder is slowed down in the presence of chloride ions.
