7
8
9 Chronic pain involves sensitization of nociceptors and synaptic transmission of painful signals in
10 nociceptive circuits in the dorsal horn of the spinal cord. We investigated the contribution of clathrin-
11 dependent endocytosis to sensitization of nociceptors by G protein-coupled receptors (GPCRs) and to
12 synaptic transmission in spinal nociceptive circuits. We determined whether therapeutic targeting of
13 endocytosis could ameliorate pain. mRNA encoding dynamin (Dnm) 1-3 and adaptor-associated protein
14 kinase 1 (AAK1), which mediate clathrin-dependent endocytosis, were localized to primary sensory
15 neurons of dorsal root ganglia of mouse and human and to spinal neurons in the dorsal horn of the mouse
16 spinal cord by RNAScope®. When injected intrathecally to mice, Dnm and AAK1 siRNA or shRNA
17 knocked-down Dnm and AAK1 mRNA in dorsal root ganglia neurons, reversed mechanical and thermal
18 allodynia and hyperalgesia, and normalized non-evoked behavior in preclinical models of inflammatory
19 and neuropathic pain. Intrathecally administered inhibitors of clathrin, Dnm and AAK1 also reversed
20 allodynia and hyperalgesia. Disruption of clathrin, Dnm and AAK1 did not affect normal motor functions
21 of behaviors. Patch clamp recordings of dorsal horn neurons revealed that Dnm1 and AAK1 disruption
22 inhibited synaptic transmission between primary sensory neurons and neurons in lamina I/II of the spinal
23 cord dorsal horn by suppressing release of synaptic vesicles from presynaptic primary afferent neurons.
24 Patch clamp recordings from dorsal root ganglion nociceptors indicated that Dnm siRNA prevented
25 sustained GPCR-mediated sensitization of nociceptors. By disrupting synaptic transmission in the spinal
26 cord and blunting sensitization of nociceptors, endocytosis inhibitors offer a therapeutic approach for pain
27 treatment.

4 **INTRODUCTION**
5
6

7
8
9 Chronic pain is common, poorly understood and difficult to treat. The analgesic properties of μ -
10 opioid agonists, a common treatment, dwindle with time and their usefulness is limited by life-threatening
11 side effects [36]. The redundancy of pain signaling, where multiple receptors and channels activate the
12 same neurons [2], may limit the effectiveness of selective ligands for the treatment of multi-modal forms
13 of pain.
14
15

16
17 We investigated the contributions of clathrin-dependent endocytosis to sensitization of nociceptors
18 and synaptic transmission in nociceptive circuits in the dorsal horn of the spinal cord. We hypothesized that
19 disruption of endocytosis would reverse multiple modalities of pain. Mediators from damaged tissues
20 activate G protein-coupled receptors (GPCRs), receptor tyrosine kinases and ligand-gated ion channels at
21 the peripheral endings of nociceptors to initiate pain [2]. The central terminals of nociceptors in the dorsal
22 horn of the spinal cord release substance P, calcitonin gene-related peptide (CGRP) and glutamate, which
23 activate GPCRs on spinal neurons that transmit signals centrally. Synaptic vesicle (SV) cycling is required
24 for synaptic transmission [6; 37]. SV exocytosis at presynaptic terminals releases neurotransmitters into the
25 synapse. Clathrin-dependent endocytosis retrieves SVs from the plasma membrane of presynaptic neurons,
26 which replenishes the releasable SV pool and is necessary for sustained neurotransmission. Dynamin (Dnm)
27 GTPase mediates fission of clathrin-coated SVs and is required for endocytosis. Of the three Dnm isoforms
28 (*Dnm1*, *Dnm2*, *Dnm3*), *Dnm1* and *Dnm3* are expressed in the nervous system [15]. *Dnm1* deletion in mice
29 impairs activity-dependent endocytosis of SVs at nerve terminals and disrupts neurotransmission during
30 intense stimulation [29]. Although *Dnm3* deletion alone does not severely disrupt synaptic transmission,
31 deletion of *Dnm3* and *Dnm1* depletes SVs and causes accumulation of clathrin-coated pits (CCPs) in
32 presynaptic terminals [29]. Dnm inhibitors recapitulate these effects [24]. Together with clathrin, adaptor
33 protein 2 (AP2) constitutes the major coated protein of the endocytic vesicles. Adaptor associated kinase 1
34 (AAK1) recruits clathrin and AP2 to the plasma membrane and phosphorylates the μ 2 subunit of AP2
35 (AP2M1), thereby stimulating cargo binding and recruitment, vesicle assembly and internalization [9].
36 Clathrin assembly promotes AAK1-dependent phosphorylation of AP2M1, which constitutes a feedforward

4 loop for pit maturation [32]. Clathrin and Dnm also mediate endocytosis and sustained endosomal signaling
5
6 of GPCRs, which underlies neuronal sensitization and nociception [18-20; 30; 40].
7

8
9 The contribution of clathrin, Dnm and AAK1 to nociception is not fully understood. A screen of
10 knockout mice identified AAK1 as a mediator and target for neuropathic pain [21]. *Aak1* deletion and
11 inhibition attenuated neuropathic pain in mice and rats. The α subunit of the AP2 complex (AP2 α 2) is
12 expressed in CGRP+ve nociceptors and AP2 shRNA suppressed nociception in mice [28]. However, the
13 distribution of Dnm and AAK1 isoforms in nociceptive circuits is unknown and their role in nociception is
14 unexplored. We used genetic and pharmacological approaches to investigate the contribution of endocytosis
15 to nociception. Anatomical, electrophysiological and behavioral studies support the hypothesis that Dnm
16 and AAK1 are necessary for sensitization of nociceptors and for nociceptive transmission in the spinal cord,
17 and that disruption of endocytosis reverses nociception.

32 **METHODS**

33 **Animals.** All experiments and procedures were in accordance with the guidelines recommended by the
34 National Institute of Health, the International Association for the study of Pain, the National Centre for the
35 Replacement, Refinement, and Reduction of Animals in Research ARRIVE guidelines, and were approved
36 by the New York University Institutional Animal Care and Use Committee and the Monash University
37 Animal Ethics Committee. Male and female C57BL/6 mice (8-10 weeks, Charles River) were housed four
38 per cage at $22 \pm 0.5^\circ\text{C}$ under a controlled 14/10 h light/dark cycle with free access to food and water. Mice
39 were randomly assigned to experimental groups, and the group size was based on our previous similar
40 studies. Investigators were blind to treatments.

51 **Collection of human tissues.** The collection of dorsal root ganglia (DRG) from deidentified organ donors
52 was reviewed by the Institutional Review Board of the University of Cincinnati (#00003152, Study ID
53 2015-5302) and was deemed to be exempt. Donor information is provided in **Table S1**. DRG (L4, L5) were
54 collected in the operating room within 90 min of aortic cross clamp and after removal of vital organs. DRG
55 were placed in N-Methyl-D-glucamine-artificial cerebrospinal fluid (ACSF) solution at 4°C and were
56
57
58

60
61
62
63
64
65

1
2
3
4 dissected as described [39]. For RNAScope, DRG were immersion fixed in 4% paraformaldehyde in
5
6 phosphate-buffered saline (PBS) overnight at 4°C, cryoprotected in 30% sucrose for 24 h at 4°C, and
7
8 embedded in Optimal Cutting Temperature (OCT) compound (Tissue Tek). Frozen sections (14 µm
9
10 sections) were mounted onto Superfrost Plus slides (Fisher), dried (15 min) and stored at -20°C.

11
12 **Collection of mouse tissues.** Mice were anesthetized (5% isoflurane) and perfused through the ascending
13
14 aorta with PBS and then 4% paraformaldehyde in PBS. DRG, trigeminal ganglia (TG) and spinal cord were
15
16 removed, post-fixed in 4% paraformaldehyde in PBS at 4°C for 1 h or overnight, respectively, placed in
17
18 30% sucrose solution for 24 h at 4°C, and embedded in OCT. Frozen sections (10-12 µm) were mounted
19
20 onto Superfrost Plus slides (Fisher), dried (15 min) and stored at -20°C.

21
22 **RNAScope® *in situ* hybridization and immunofluorescence.** The RNAScope® system (Advanced Cell
23
24 Diagnostics) was used per manufacturer's directions for fresh-frozen tissue except for omission of the initial
25
26 on-slide fixation step. Probe hybridization and detection using the Multiplex Fluorescent Kit v2 followed
27
28 the manufacturer's directions. Probes to *Mm-Dnm1* (#446931-C3), *Mm-Dnm2* (#451831-C1), *Mm-Dnm3*
29
30 (#451841-C2), *Mm-Aak1* (#1097711-C1) (mouse), *Hs-Dnm1* (#1099091-C1), *Hs-Dnm2* (#821511-C1),
31
32 *Hs-Dnm3* (#1105961-C2) and *Hs-AAK1* (#531971-C1) (human) were used. Sections were incubated with
33
34 Opal 620 reagent (1:1000, cat#FP1495001KT, Akoya Biosciences) for detection. To detect neurons,
35
36 hybridized slides were incubated with NeuroTrace™ 500/525 Green Fluorescent Nissl Stain (1:500,
37
38 cat#N21480, Invitrogen) (10 min, room temperature, RT). To detect satellite glial cells and peptidergic
39
40 neurons, hybridized slides were incubated with rabbit anti-glutamine synthetase antibody (GS, 1:1000,
41
42 cat#ab49873, Abcam, Cambridge, MA) or rabbit anti-CGRP, 1:1000, cat#C8198, Sigma), respectively
43
44 (overnight, 4°C). Slides were washed and incubated with goat anti-rabbit Alexa Fluor® 488 (1:1000;
45
46 cat#A21206, Invitrogen) (1 h, RT). Slides were washed and incubated with DAPI (1 µg/ml, 5 min) and
47
48 mounted in ProLong® Gold Antifade (Thermo Fisher). Sections were observed using a Leica SP8 confocal
49
50 microscope with HCX PL APO 40x (NA 1.30) oil objective.

51
52 **RNAScope® quantification.** *Dnm 1, 2 or 3* and *Aak1* were localized by RNAScope®. Confocal images
53
54 were analyzed using Fiji ImageJ (NIH) according to ACD Bio-Techne Technical Note. Regions of interest
55
56
57

1
2
3
4 were defined by applying a threshold with the moments setting (Min & Max) and analyzing particles with
5
6 size range from 0 to infinity. Regions of interest were overlaid on the original micrograph and the number
7
8 of dots per area were quantified. Results are expressed as dots/mm² tissue. A total of 3 images (20X
9
10 magnification) were analyzed for each mouse (N=4 mice for control and treatment groups; 12 images
11
12 analyzed per experimental group).
13

14
15 **qRT-PCR.** RNA was isolated from snap frozen mouse tissues using Direct-zol RNA MiniPrep kit
16
17 (cat#R2051 Zymo Research). cDNA was prepared using MultiScribe Reverse Transcriptase (cat#4311235
18
19 Thermo Fisher). cDNA (50 ng) was amplified for 40 cycles by quantitative real-time reverse transcription
20
21 polymerase chain reaction (qRT-PCR) using Dnm1 (DNM1, Mn00802468_m1), Dnm2 (DNM2,
22
23 Mn00514582_m1), Dnm3 (DNM3, Mn00554098_m1), AAK1 (Mn01183675_m1) and GAPDH
24
25 (Mn99999915_g1) primers, QuantStudio 3 Real-Time PCR System, and TaqMan Fast Advanced PCR
26
27 Mastermix (cat#4444556 Thermo Fisher). All samples were analyzed at least in duplicate and normalized
28
29 by GAPDH expression. The relative expression ratio per condition was calculated as described [27].
30
31

32
33 **Intrathecal administration of siRNA to mice.** Cationic liposome and adjuvant anionic polymer
34
35 (polyglutamate) were used to deliver siRNA [35]. The following siRNAs were used: ON-TARGETplus
36
37 siRNA mouse Dnm1 siRNA (cat#L-043277-01-0005), mouse Dnm2 (cat#L-044919-02-0005), mouse
38
39 Dnm3 (cat#L-059061-01-0005), mouse AAK1 (cat#L-065639-00-0005) or non-targeting control (CTR)
40
41 siRNA (cat#D-001810-10-05) (Dharmacon) (**Table S2**). siRNAs (50 ng, 0.5 µl of 100 ng/µl stock) were
42
43 mixed with 0.5 µl of adjuvant polyglutamate (0.1 µg/µl stock) and 1.5 µl sterile 0.15 M NaCl. Liposome
44
45 solution, cationic lipid 2-3-[bis-(3-amino-propyl)-amino]-propylamino-N-ditetradecylcarbamoymethyl-
46
47 acetamide (DMAPAP) and L- α -dioleoyl phosphatidylethanolamine (DOPE) (DMAPAP/DOPE, 1/1 M:M)
48
49 (2.5 µl of 200 µM) was added to siRNA/adjuvant, vortexed for 1 min, and incubated (30 min, RT). The
50
51 siRNA lipoplexes were administered to conscious mice by intrathecal (i.t.) injection (L4-L5, 5 µl), 24 h
52
53 after CFA intraplantar (i.pl.) injection or 10 d after SNI surgery. *Dnm1*, *Dnm2*, *Dnm3* and *Aak1* expression
54
55 in DRG and spinal cord (L4-L5) were analyzed by RNAScope® in situ hybridization, 24 or 48 h after
56
57 siRNA injection. For electrophysiology experiments, mouse Dnm1 siRNA, mouse AAK1 siRNA or CTR
58
59
60
61
62
63
64
65

1
2
3
4 siRNA were mixed with PEI (cat#765090, Sigma) and incubated for 10 min at RT. The siRNA-PEI
5
6 complex was diluted in saline and 5 μ l was injected i.t. into mice 48 h before laminectomy for spinal slice
7
8 preparation.

9
10 **Intrathecal administration of shRNA to mice.** Mouse Dnm1 (cat# TL500548), AAK1 (cat# TL508098)
11
12 shRNA plasmids and noneffective 29-mer scrambled shRNA cassette in pGFP-C-shLenti Vector were from
13
14 OriGene (**Table S2**). The Dnm1 shRNA or AAK1 shRNA (1.25 μ g) was mixed with polyethyleneimine-
15
16 based transfection reagent (in vivo-jetPEI®, 201-50G; Polyplus) in an 8:1 N:P ratio (polyethyleneimine
17
18 nitrogen to DNA phosphate ratio) [8]. The shRNAs in vivo-jetPEI® mixture were administered to
19
20 conscious mice by i.t. injection (L4-L5, 5 μ l), 24 h after CFA injection (i.pl.) or 10 d after SNI surgery.
21
22 Dnm1 and Aak1 expression in DRG (L4-L5) were analyzed by RNAScope® in situ hybridization, 72 h
23
24 after shRNA injection.
25
26

27
28 **Intrathecal administration of endocytosis inhibitors to mice.** Dyngo4a (Dnm inhibitor, 50 nM), PitStop2
29
30 (clathrin inhibitor, 50 nM), inactive analogs (trademarks of Children's Medical Research Institute,
31
32 Newcastle Innovation and Freie Universitat Berlin), LP935509 (AAK1 inhibitor, cat#HY-117626,
33
34 MedChemExpress; 1 – 10 μ g/5 μ l), SGC-AAK1-1 (AAK1 inhibitor, cat#6528, Tocris; 1 – 10 μ g/5 μ l) or
35
36 vehicle (PBS, 5%DMSO/PBS) was injected i.t. (5 μ l, L4/L5) into conscious mice. The inhibitors were
37
38 injected 48 h after CFA injection (i.pl.) or 10 d after SNI surgery.
39
40

41
42 **Inflammatory pain.** Complete Freund's Adjuvant (CFA) (1 mg/ml) or vehicle (0.9% NaCl) was
43
44 administered by i.pl. injection (10 μ l) into the right hindpaw of sedated mice (2% isoflurane). siRNA,
45
46 shRNA or inhibitors were injected i.t. 24 h or 48 h after CFA. Mechanical allodynia and thermal
47
48 hyperalgesia were assessed.
49

50
51 **Neuropathic pain.** Spared Nerve Injury (SNI) and sham surgeries were made as described [26]. Briefly,
52
53 mice were anesthetized with isoflurane. A skin and muscle incision were made in the thigh to expose the
54
55 sciatic nerve innervating the left hindpaw. The tibial and common peroneal nerves were ligated and
56
57 transected distal to the ligature. The third branch, the sural nerve, was left intact. For sham controls, the
58
59
60
61
62
63
64
65

1
2
3
4 nerves were exposed but not ligated or transected. siRNA, shRNA or inhibitors were injected i.t. at 10 d
5
6 after surgery. Mechanical and cold allodynia were assessed.

7
8
9 **Mechanical allodynia.** Mechanical allodynia was assessed by measuring hindpaw withdrawal response to
10 von Frey filament stimulation using the up-and-down method [13]. Mice were acclimatized to the testing
11 apparatus, which comprised individual clear Plexiglass boxes on an elevated wire mesh platform to
12 facilitate access to the plantar surface of the hindpaws, for 1 h/d for 2 d. A series of von Frey filaments
13 (0.02, 0.07, 0.16, 0.4, 1.0, and 2 g; Stoelting) were applied perpendicular to the plantar surface of hindpaw.
14
15
16
17
18
19 The test began with an application of 0.4 g filament. A positive response was defined as a clear paw
20 withdrawal or shaking. Whenever a positive response occurred, the next lower filament was applied, and
21
22 whenever a negative response occurred, the next higher filament was applied. The testing consisted of 6
23
24 stimuli, and the pattern of response was converted to a 50% von Frey threshold [7].
25
26
27

28
29 **Thermal hyperalgesia.** The Hargreaves apparatus was used to evaluate hypersensitivity to heat (Ugo
30 Basile) [17]. Mice were acclimatized to the testing apparatus, which comprised individual clear Plexiglass
31 chambers and a radiant heat source, for 1 h/d for 2 d. The infrared intensity was set at 50% and cut off time
32 to a maximum of 30 s. The time between stimulus onset and paw withdrawal was measured automatically,
33
34 giving an index of the thermal nociceptive threshold. Significant decreases in paw withdrawal latency were
35
36 interpreted as evidence of thermal hyperalgesia. The latency, expressed in seconds, was evaluated before
37
38 (basal) and at different time points after the treatment.
39
40
41
42

43
44 **Cold allodynia.** Cold allodynia was assessed by measuring the acute nociceptive response to the acetone
45 evoked evaporative cooling [38]. A droplet (50 μ L) of acetone, formed on the flat-tip needle of a syringe,
46
47 was gently touched to the plantar surface of the mouse hind paw. The time spent licking and lifting of the
48
49 paw over a period of 60 s was evaluated before (basal) and at different time points after the treatment.
50
51

52
53 **Non-evoked behavior.** Non-evoked behavior of mice was assessed using a behavioral spectrometer
54 (Behavioral Instruments), a validated instrument for phenotyping rodents that avoids operator bias [3].
55
56 This approach has been used for studies of abhorrent behavior in mouse models of autism, restraint stress,
57
58 and inflammatory, neuropathic and visceral pain [3; 5; 23]. The spectrometer comprised a 40 cm² arena
59
60
61
62
63
64
65

1
2
3
4 with a CCD camera mounted in the center of the ceiling and a door aperture in the front area of the arena.
5
6 Movement was assessed by a floor mounted vibration sensor and 32 wall mounted infrared transmitter and
7
8 receiver pairs. Mice were individually placed in the center of the behavioral spectrometer and their behavior
9
10 was recorded for 20 min and analyzed using a combination of video tracking analysis (Viewer3, BiObserve)
11
12 and vibration analysis. Total distance traveled in the open field (number of visits to a central area), average
13
14 velocity of locomotion (cm/s), track length (cm), ambulation (% activity), time engaged in grooming (min),
15
16 and wall distance (cm) were recorded and analyzed as described [3].

Spinal slice preparation. Adult C57BL/6J mice were anesthetized (5% isoflurane), decapitated and the lumbar region of the spinal cord with the dorsal root exposed by laminectomy was removed. Parasagittal spinal cord slices with the dorsal root attached (300 μ m) were sectioned on a vibratome (Leica VT 1200s) in ice cold (0-4°C) oxygenated sucrose- based ACSF that contained (mM): 100 sucrose, 63 NaCl, 2.5 KCl, 1.2 NaH₂PO₄, 1.2 MgCl₂, 25 glucose, 25 NaHCO₃ and 5 Na ascorbate. Slices were then incubated for 15 min at 34°C in NMDG- based recovery ACSF composed of (mM): 93 NMDG, 2.5 KCl, 1.2 NaH₂PO₄, 30 NaHCO₃, 20 HEPES, 25 glucose, 5 Na ascorbate, 2 thiourea, 3 Na pyruvate, 10 MgSO₄ and 0.5 CaCl₂ and adjusted to pH 7.4 with HCl. After the recovery incubation, slices were transferred to oxygenated ACSF with the following composition (mM): 125 NaCl, 2.5 KCl, 1.25 NaH₂PO₄, 1.2 MgCl₂, 2.5 CaCl₂, 25 glucose and 25 NaHCO₃ for 45 min at 36°C and then maintained at RT prior to transfer to the recording chamber. All ACSF solutions were equilibrated with 95% O₂ and 5% CO₂. Spinal cord slices were collected 48 h after administration of siRNA (i.t.). Some slices were preincubated with inhibitors of Dnm (Dyngo4a, 30 μ M) or AAK1 (SGC-AAK1-1, 100 nM; LP-935509, 1 μ M) for 10 min.

Spinal cord electrophysiology. Slices were transferred to the recording chamber and continuously superfused with ACSF equilibrated with 95% O₂/5% CO₂ at a rate of 2ml/min at RT. Dodt-contrast optics were used to identify dorsal horn neurons in the translucent substantia gelatinosa layer of the superficial dorsal horn. Evoked and spontaneous excitatory post-synaptic currents (eEPSCs, sEPSCs respectively) were recorded in whole-cell voltage clamp using a CsCl-based internal solution composed of (mM): 140 CsCl, 10 EGTA, 5 HEPES, 2 CaCl₂, 2 MgATP, 0.3 NaGTP, 5 QX-314.Cl and 0.1% biocytin (osmolarity

1
2
3
4 285–295 mosmol/l). Patch clamp electrodes had resistances between 3-5 MΩ and neurons were held at -65
5
6 mV (not corrected for the liquid junction potential of 4 mV). A bipolar stimulating electrode was placed in
7
8 the dorsal root entry zone for electrical stimulation of evoked post-synaptic currents. For paired pulse
9
10 experiments, evoked currents were elicited by two consecutive stimuli of identical strength separated by 40
11
12 ms. Paired pulse ratio (PPR) was calculated by dividing the second pulse by the first (PSC2/PSC1). All
13
14 eEPSCs were recorded in gabazine (10 μM) and strychnine (0.5 μM). In experiments with endocytosis
15
16 inhibitors, baseline recordings were made prior to superfusion of with inhibitors for 10 min, after which
17
18 recordings were repeated in the presence of the inhibitor. In the inhibitor studies, the 1Hz protocol was
19
20 reduced to 8 pulses to prevent plastic changes at the synapse occurring between the baseline recording and
21
22 post-inhibitor recording.
23
24

25
26 **SV imaging.** Lumbar spinal cord slices were incubated in Mg²⁺-free ACSF that contained (mM): 125 NaCl,
27
28 2.5 KCl, 1.25 NaH₂PO₄, 25 NaHCO₃, 2.5 CaCl₂, 10 glucose and 0.1 4-AP for 10 min to increase neuronal
29
30 activity. Slices were transferred to Mg²⁺-free ACSF with 4-AP containing 8 μM FM1-43 (Abcam,
31
32 Australia) for 3 min, washed with ACSF for 2 min, and then incubated in 1 mM ADVASEP-7 (Sigma) for
33
34 2 min. Slices were washed with ACSF for 2 min and the ADVASEP-7 incubation was repeated. Slices were
35
36 placed in the recording chamber and washed for a further 15 min in ACSF prior to imaging. A bipolar
37
38 stimulating electrode was placed in the dorsal root entry zone of the spinal cord and stimulated for 10 s at
39
40 1Hz, 4-6V to facilitate the release of vesicles from the presynaptic terminals. Optical recordings were
41
42 completed on an upright fluorescence microscope (BX51W1, Olympus) under 40x magnification using a
43
44 Cy3/TRITC filter set CCD camera (C11440 Orca Flash 4.0, Hamamatsu). Image sequences were analyzed
45
46 using Fiji NIH image software.
47
48

49
50 **Transmission electron microscopy.** Adult C57BL/6 mice were treated with Dnm1 or CTR siRNA (i.t.).
51
52 After 48 h, mice were anaesthetized (5% isoflurane), decapitated and the lumbar region of the spinal cord
53
54 exposed by laminectomy and removed. Spinal cord slices were prepared and a bipolar stimulating electrode
55
56 was placed in the dorsal root entry zone for electrical stimulation of evoked post-synaptic currents. Spinal
57
58 cord sections were fixed in 2% paraformaldehyde, 2.5% glutaraldehyde, 0.1M sucrose in 0.1M MBP (pH
59
60
61
62
63
64
65

1
2
3
4 7.4). Sections were post-fixed in 1% OsO₄ and 1.5% K₄Fe(CN)₆ in ddH₂O, dehydrated in graded series of
5
6 ethanol and propylene oxide, and embedded in EMbed 812 (Electron Microscopy Sciences). Ultrathin
7
8 sections (70 nm) were cut and stained with uranyl acetate and lead citrate. Stained grids were imaged with
9
10 Talos120C transmission electron microscope (Thermo Fisher Scientific) and recorded using Gatan (4k x
11
12 4k) OneView Camera with software Digital Micrograph (Gatan Inc., Pleasanton, CA). Morphometry
13
14 measurements were made using Image J by an investigator blinded to the experimental conditions. For
15
16 analysis of SV numbers, 10331 vesicles in total from 212 Dnm1 siRNA and 182 CTR siRNA synapses
17
18 from 2 separate preparations. To eliminate bias that could arise from choosing synapses based on their size
19
20 or SV number, synapses were selected based on the presence of an active zone. All SVs within the adjacent
21
22 SV cluster were then counted. In experiments designed to assess the effects of Dnm1 siRNA treatment on
23
24 the abundance of CCPs, 13276 vesicles (CCP + SV) in total were counted; results were expressed as the
25
26 percentage of CCPs relative to the total of SVs + CCPs/synapse (n=212 Dnm1 siRNA and 182 CTR siRNA
27
28 synapses).

29
30
31
32 **Trypsin-evoked nociception.** Dnm1+2+3 or CTR siRNA was administered by i.t. injection as described
33
34 above. After 48 h, trypsin (10 µl, 80 nM) was injected (i.pl.) into the right hindpaw. Mechanical allodynia
35
36 was assessed 1 h after trypsin injection [20].

37
38
39 **Trypsin-evoked hyperexcitability of nociceptors.** Dnm1+2+3 or CTR siRNA was administered by i.t.
40
41 injection as described above. After 48 h, DRG (L3-L5) were removed and dispersed by incubation in
42
43 collagenase (4 mg/ml, Gibco) and dispase (4.7 mg/ml, Gibco) for 15 min at 37 °C and triturated with a 200
44
45 µL pipette tip. Neurons were plated onto coverslips coated with laminin (0.013 mg/ml) and poly-L-ornithine
46
47 (0.1 mg/ml) in 12-well plates. Neurons were cultured in F12 medium (Sigma) containing 10% fetal bovine
48
49 serum, penicillin and streptomycin and maintained at 37°C in a humidified atmosphere of 95% air and 5%
50
51 CO₂ until retrieval (16 h) for patch clamp recordings. Small-diameter (<30 µm) neurons were selected for
52
53 patch clamp recording. Changes in excitability were quantified by measuring rheobase. Whole-cell
54
55 perforated patch-clamp recordings were made using Amphotericin B (240 µg/ml, Sigma Aldrich) in current
56
57 clamp mode at RT. The recording chamber was perfused with external solution at 2 ml/min. Recordings
58
59
60
61
62
63
64
65

1
2
3
4 were made using Multiclamp 700B amplifiers, digitized by Digidata 1440A, and processed using pClamp
5
6 10.7 software (Molecular Devices). Solutions had the following composition (mM): pipette - K-gluconate
7
8 110, KCl 30, HEPES 10, MgCl₂ 1, CaCl₂ 2; pH 7.25 with 1 M KOH; external - NaCl 140, KCl 5, HEPES
9
10 10, glucose 10, MgCl₂ 1, CaCl₂ 2; pH to 7.3-7.4 with 1 M NaOH. Neurons were preincubated with trypsin
11
12 (100 nM) for 10 min and washed. Rheobase was measured at T=0 or T=30 min after washing.
13

14
15 **Statistics.** Data are presented as mean ± standard error of the mean (SEM). Groups of n=6 to 10 mice were
16
17 studied. Differences were assessed using Student's two-tailed t test for two comparisons and 1- or 2-way
18
19 ANOVA and Sídák, Tukey, Newman-Keuls or Dunnett's post-hoc test for multiple comparisons. P<0.05
20
21 was considered significant at the 95% confidence level. Sample sizes and statistical tests are specified in
22
23 figure legends.
24

25 26 27 28 **RESULTS**

29 30 31 **Dnm1 and Dnm3 are expressed in neurons of sensory ganglia and the spinal cord dorsal horn**

32
33 We used RNAScope® *in situ* hybridization to localize isoforms of *Dnm1*, *Dnm2* and *Dnm3* mRNAs
34
35 in DRG, TG and spinal cord of mice. Neurons were identified by Nissl staining. Immunostaining for CGRP
36
37 allowed identification of a subset of small diameter peptidergic nociceptors of sensory ganglia [2].
38
39 CGRP+ve nociceptors express AP2α2, a key endocytosis protein that contributes to nociception [28].
40
41 Satellite glial cells of sensory ganglia were identified by immunostaining for GS. *Dnm1* and *Dnm3* mRNAs
42
43 were expressed in neurons of DRG and TG (**Fig. 1A; Fig. S1A**). *Dnm2* mRNA was detected in DRG and
44
45 TG neurons at lower levels (**Fig. 1A; Fig. S1A**). Although *Dnm1*, *Dnm2* and *Dnm3* mRNAs were detected
46
47 in CGRP+ve nociceptors (**Fig. S2**), Dnm isoforms were expressed in most neurons regardless of CGRP
48
49 expression and diameter. Dnm isoforms were also found in non-neuronal cells within sensory ganglia,
50
51 including GS+ve satellite glial cells (**Fig. 1A**). *Dnm1* and *Dnm3* mRNAs were mainly detected in neurons
52
53 of deeper laminae of the dorsal horn of the spinal cord, although some neurons with cell bodies in the
54
55 superficial laminae (LI, LII, LIII) also expressed *Dnm1* and *Dnm3* mRNAs (**Fig. 1B**). Fewer neurons in the
56
57 spinal cord expressed *Dnm2* mRNA. Analysis of extracts of DRG, TG and spinal cord by qRT-PCR
58
59
60
61
62
63
64
65

1
2
3
4 confirmed the higher levels of expression of *Dnm1* and *Dnm3* compared to *Dnm2* mRNA (**Fig. 1C, D; Fig.**
5
6 **S1B**). *Dnm1* and *Dnm3* mRNAs were also localized to neurons of human DRG (**Fig. 1E**), which adds
7
8 translational relevance to these findings.
9

10 **Dnm siRNA knockdown in DRG reverses inflammatory and neuropathic pain**

11
12 To study the contribution of Dnm isoforms to nociception, we administered (i.t. injection) Dnm1,
13
14 Dnm2, Dnm3 or CTR siRNAs to mice. RNAScope® revealed that Dnm siRNA inhibited expression of
15
16 *Dnm1*, *Dnm2* and *Dnm3* mRNA in DRG neurons after 48 h compared to CTR siRNA (**Fig. 2A, B**), while
17
18 expression in the spinal cord was unaffected (**Fig. S3A, B**).
19

20
21 We investigated the effects of Dnm knockdown in a preclinical model of inflammatory pain in mice
22
23 induced by injection of CFA or vehicle (control) into the hindpaw (**Fig. 2C**). Dnm1, Dnm2, Dnm3 or CTR
24
25 siRNA was administered 24 h after CFA. Withdrawal responses of the CFA-injected (left, ipsilateral) and
26
27 non-injected (right, contralateral) hindpaws to stimulation with von Frey filaments and radiant heat were
28
29 assessed daily to evaluate mechanical allodynia and thermal hyperalgesia, respectively. CFA-induced
30
31 inflammation reduced both the withdrawal threshold to von Frey filaments and the withdrawal latency to
32
33 heat in the ipsilateral paw for at least 4 d, consistent with mechanical allodynia and thermal hyperalgesia
34
35 (**Fig. 2D, E; Fig. S4A, B**). Dnm1, Dnm2 or Dnm3 siRNAs partially reversed mechanical allodynia to a
36
37 similar degree after 24 and 48 h, with a larger effect at 48 h when compared to CTR siRNA (**Fig. 2D**).
38
39 When administered together, Dnm1+2+3 siRNAs reversed mechanical allodynia to 72±15% of baseline at
40
41 48 h ($P<0.0001$ compared to CTR siRNA). Dnm1, Dnm2 or Dnm3 siRNAs reversed thermal hyperalgesia
42
43 after 24 and 48 h, with a larger effect at 24 h (**Fig. 2E**). Dnm1+2+3 siRNAs reversed thermal hyperalgesia
44
45 by 100±4% at 24 h ($P<0.0001$). The anti-nociceptive actions of Dnm siRNA were lost after 72 h (**Fig. S4A,**
46
47 **B**). None of the treatments (i.pl. CFA, i.t. siRNAs) affected withdrawal responses of the contralateral (non-
48
49 injected) paw to mechanical stimuli (**Fig. S4C-F**).
50
51
52
53
54

55
56 Neuropathic pain was induced by SNI surgery of the hindpaw, which induces allodynia; control
57
58 mice underwent sham surgery. Dnm1, Dnm2, Dnm3 or CTR siRNA was administered (i.t. injection) 10 d
59
60
61
62
63
64
65

1
2
3
4 after surgery and withdrawal responses of the operated (ipsilateral) and non-operated (contralateral)
5
6 hindpaws to von Frey filaments and cold were assessed daily to evaluate mechanical and cold allodynia,
7
8 respectively (**Fig. 3A**). Dnm1 siRNA reversed mechanical and cold allodynia after 24 and 48 h when
9
10 compared to CTR siRNA, although the inhibitory effects were lost after 72 h (**Fig. 3B**). Dnm1+2+3 siRNAs
11
12 strongly inhibited mechanical and cold allodynia at 24, 48 and 72 h (**Fig. 3C**). The largest effect on
13
14 mechanical allodynia was after 48 h, when the response was $42\pm 5\%$ of baseline ($P<0.0001$). The largest
15
16 effect on cold allodynia was after 24 h, when the response was $70\pm 6\%$ of baseline ($P<0.0001$). None of the
17
18 treatments (SNI surgery, i.t. siRNA) affected withdrawal responses of the contralateral (non-operated) paw
19
20 to mechanical stimuli (**Fig. S5A**).

21
22
23
24 Non-evoked behavior was assessed using a behavioral spectrometer. Behavior was monitored for
25
26 20 min at 48 h after administration (i.t. injection) of Dnm or CTR siRNA into SNI and sham mice. In mice
27
28 receiving CTR siRNA, the number of visits to the center area was reduced in SNI compared to sham mice
29
30 (**Fig. 3D, E**). Dnm1+2+3 siRNAs normalized the number of visits to the center area in SNI mice but had
31
32 no effects in sham mice. In sham mice, Dnm1+2+3 siRNAs did not affect average velocity, track length,
33
34 total activity, ambulation, grooming or wall distance when compared with CTR siRNA (**Fig. S5B**).

35 36 37 **AAK1 siRNA knockdown in DRG reverses inflammatory and neuropathic pain**

38
39
40 RNAScope® revealed *Aak1* mRNA in neurons of DRG, TG and spinal cord dorsal horn (**Fig. 4A;**
41
42 **Fig. S1A**). Although *Aak1* mRNA was detected in CGRP+ve peptidergic nociceptors of DRG, most neurons
43
44 expressed *Aak1* mRNA regardless of CGRP content or diameter (**Fig. 4B**). *Aak1* mRNA was also detected
45
46 in GS+ve satellite glial cells of sensory ganglia. qRT-PCR analyses confirmed expression of *Aak1* mRNA
47
48 in DRG, TG and spinal cord (**Fig. 4C**). AAK1 mRNA was also localized to neurons of human DRG (**Fig.**
49
50 **4D**).

51
52
53
54 AAK1 siRNA (i.t. injection) depleted *Aak1* mRNA in DRG neurons after 24 h compared to CTR
55
56 siRNA, determined by RNAScope® (**Fig. 5A, B**); *Aak1* expression in the spinal cord was unaffected (**Fig.**
57
58 **S3A, B**). To evaluate effects on nociception, AAK1 or CTR siRNA was administered (i.t. injection) to mice
59
60
61
62
63
64
65

1
2
3
4 24 h after CFA or 10 d after SNI surgery (**Fig. 5C, D**). AAK1 siRNA partially reversed CFA-evoked
5
6 mechanical allodynia and almost completely reversed thermal hyperalgesia when compared to CTR siRNA
7
8
9 (**Fig. 5C**). AAK1 siRNA reversed mechanical allodynia to $52\pm 9\%$ of baseline ($P<0.0001$ compared to CTR
10
11 siRNA) and thermal hyperalgesia to $92\pm 6\%$ of baseline ($P<0.01$) after 48 h. AAK1 siRNA partially
12
13 reversed SNI-evoked mechanical and cold allodynia (**Fig. 5D**). AAK1 siRNA reversed mechanical
14
15 allodynia to $28\pm 4\%$ of baseline at 48 h ($P<0.01$) and reversed cold allodynia to $54\pm 8\%$ of baseline at 24 h
1
17 ($P<0.01$). AAK1 siRNA did not affect withdrawal responses of the contralateral paw (**Fig. S6A, B**). In mice
18
19 receiving CTR siRNA, the number of visits to the center area of the field was reduced in SNI compared to
20
21 sham mice. AAK1 siRNA restored the number of visits to the center area in SNI mice but had no effects in
22
2 sham mice. AAK1 siRNA did not affect any measured behavior (**Fig. S6C**).

64
65
Inhibitors of endocytosis offer a pharmacological approach for pain management. To investigate
this hypothesis, we examined the effects of inhibitors of Dnm (Dyngo4a) [33], clathrin (PitStop2) [34] and
AAK1 (LP935509 [21], SGC-AAK1-1 [1]) on inflammatory and neuropathic pain.

Dyngo4a, PitStop2, inactive analogs (control) (5 μ l, 50 μ M), LP935509, SGC-AAK1-1 (5 μ l, 1 -
10 μ g) or vehicle (control) was administered (i.t. injection) 48 h after CFA (**Fig. 6A**). Dyngo4a partially
reversed mechanical allodynia and thermal hyperalgesia when compared to vehicle, with a maximum
inhibitory effect at 1 h of $80\pm 11\%$ for mechanical allodynia ($P<0.0001$ compared to vehicle) and $75\pm 6\%$
for thermal hyperalgesia ($P<0.05$) (**Fig. 6B, C**). PitStop2 reversed CFA-evoked mechanical allodynia and
thermal hyperalgesia similarly to Dyngo4a (**Fig. 6B, C**). LP935509 dose-dependently inhibited mechanical
allodynia, with a maximal effect for 10 μ g at 2 h of $78\pm 8\%$ of baseline ($P<0.0001$) (**Fig. 6D**). LP935509
almost completely reversed thermal hyperalgesia, with a maximal effect for 10 μ g at 2 h of $89\pm 7\%$ of
baseline ($P<0.0001$) (**Fig. 6E**). Likewise, SGC-AAK1-1 reversed CFA-evoked mechanical allodynia and
thermal hyperalgesia similarly to LP935509 (**Fig. 6F, G**).

1
2
3
4 Inhibitors of Dnm, clathrin or AAK1 were administered (i.t. injection) 10 d after SNI surgery (**Fig.**
5
6 **6H**). Dyngo4a reversed SNI-evoked mechanical and cold allodynia with a maximum inhibitory effect at 1
7
8 h of $61\pm 10\%$ of baseline for mechanical and $69\pm 8\%$ of baseline for cold allodynia ($P<0.01$) (**Fig. 6I, J**).
9 PitStop2 similarly reversed SNI-induced mechanical and cold allodynia (**Fig. 6I, J**). LP935509 and SGC-
10
11 AAK1-1 partially reversed SNI-evoked mechanical and cold allodynia from 1- 4 h (**Fig. 6K-N**). Maximal
12
13 inhibitory effects of LP935509 (10 μ g) were at 2 h for mechanical allodynia ($79\pm 9\%$ of baseline, $P<0.0001$)
14
15 and 1 h for cold allodynia ($61\pm 8\%$ of baseline, $P<0.0001$).

16
17
18
19 Inactive analogs of Dyngo4a and PitStop2 or vehicle did not affect CFA- or SNI-evoked allodynia
20
21 or hyperalgesia. None of the treatments affected withdrawal responses of the contralateral paw to
22
23 mechanical stimuli (**Fig. S7A-F**).

24 25 26 **Dnm1 and AAK1 shRNA knockdown induces long-lasting reversal of inflammatory and neuropathic** 27 28 **pain**

29
30 To determine whether a more sustained knockdown of Dnm or AAK1 would have a larger and
31
32 longer-lasting antinociceptive effect, we administered Dnm1, AAK1 or CTR shRNA to mice (i.t. injection).
33
34 Dnm1 and AAK1 shRNA depleted *Dnm1* mRNA by $42\pm 6\%$ and *Aak1* mRNA by $28\pm 4\%$ (both $P<0.01$ to
35
36 CTR), respectively, in DRG neurons after 72 h, determined by RNAScope®. Dnm1, AAK1 or CTR shRNA
37
38 was administered to mice 24 h after CFA or 10 d after SNI surgery. Dnm1 and AAK1 shRNA caused a
39
40 long-lasting reversal of CFA-evoked and SNI-evoked nociception that was fully sustained for at least 7 d
41
42 (**Fig. 7A, B**). In CFA-treated mice, Dnm1 and AAK1 shRNA, respectively, reversed mechanical allodynia
43
44 to $78\pm 8\%$ and $71\pm 6\%$ of baseline ($P<0.0001$ compared to CTR shRNA) and thermal hyperalgesia to $86\pm 4\%$
45
46 and $83\pm 4\%$ of baseline ($P=0.0001$; $P=0.001$) after 72 h. In SNI mice, Dnm1 and AAK1 shRNA respectively
47
48 reversed mechanical allodynia to $69\pm 11\%$ and $41\pm 5\%$ of baseline ($P<0.0001$ compared to CTR shRNA)
49
50 and cold allodynia to $79\pm 4\%$ and $97\pm 3\%$ of baseline ($P<0.0001$) after 72 h (**Fig. 7D**). Dnm1 or AAK1
51
52 shRNA did not affect withdrawal responses of the contralateral paw to mechanical stimulation, heat or cold
53
54 (**Fig. S8A, B**).

1
2
3
4 Thus, Dnm and AAK1 siRNA, shRNA and inhibitors reverse nociception in preclinical models of
5
6 inflammatory and neuropathic pain without discernable effects on normal motor functions or behavior.

7
8
9 **Dnm1 siRNA increases the threshold required to elicit dorsal root evoked synaptic currents in spinal**
10 **neurons**

11
12 To investigate the contribution of Dnm to synaptic transmission in nociceptive circuits, dorsal root-
13 evoked synaptic currents were recorded from spinal neurons in parasagittal slice preparations of mouse
14
15 spinal cord 48 h after injection of Dnm1 or CTR siRNA (i.t.). Dorsal roots were stimulated and eEPSCs
16
17 were recorded in whole cell voltage clamp in superficial dorsal horn (lamina I-II) neurons. The stimulus
18
19 was incrementally increased from 1-10 V to assess the stimulus intensity required to elicit a synaptic
20
21 response. The threshold voltage required to stimulate an eEPSC was higher in the Dnm1 siRNA group
22
23 compared to the CTR siRNA group, and current amplitudes were higher in the control group at lower
24
25 stimulus strength (**Fig. 8A, B**), which may be due to increased release probability at higher stimulus
26
27 intensities and recruitment of high threshold fibers. In the control group, the 50% maximal eEPSC
28
29 amplitude was 2.7 V and maximal amplitude was 5 V, above which the responses were not significantly
30
31 different from one another. In the Dnm1 siRNA group, the 50% maximal eEPSC amplitude was 4.26 V and
32
33 the maximal eEPSC amplitude was 6 V (repeated measures 1-way ANOVA, with Sidak's multiple
34
35 comparisons test).

36
37
38 **Dnm1 siRNA reduces the probability of SV release and prevents sustained SV release from**
39 **presynaptic primary afferent neurons**

40
41 To investigate the effect of Dnm1 knockdown on the probability of SV release and to determine
42
43 the contribution of pre- or post-synaptic sites, we measured paired pulse ratios of eEPSCs in superficial
44
45 neurons using a paired dorsal root stimulation at 40 ms intervals. Compared to controls, the paired pulse
46
47 ratio was depressed in the Dnm1 siRNA group ($P=0.0042$, Mann Whitney test), which indicates a
48
49 presynaptic mechanism caused by a reduction in release probability from primary afferent neurons (**Fig.**
50
51 **8C, D**). The prominent expression of *Dnm1* mRNA in DRG neurons and the preferential knockdown of
52
53 *Dnm1* mRNA in DRG neurons support a presynaptic mechanism.

1
2
3
4 Since a reduction in release probability is likely to affect the sustained responses to repetitive
5
6 stimuli, we tested the eEPSC responses to 1 Hz stimulation of the dorsal roots. A 1 Hz frequency was
7
8 chosen to allow repetitive activation of the slower latency C-fibers, which would be lost at higher
9
10 frequencies, as well as A-fiber mediated signals. In spinal cord from mice treated with CTR siRNA,
11
12 consistent eEPSC amplitudes were observed throughout the 80 s train of stimuli, whereas the eEPSC
13
14 amplitudes rapidly decreased after repeated stimulation in the *Dnm1* siRNA group (**Fig. 8E, F**). This
15
16 decrease was most apparent within the first 10 stimuli, where normalized amplitudes were significantly
17
18 different between the two groups by the 6th stimulus (**Fig. 8G**).

19
20
21
22 Styryl dyes can be used to observe SV recycling [10]. Dye molecules reversibly partition into the
23
24 plasma membrane outer leaflet but do not penetrate cells due to cationic charge. Upon stimulation and
25
26 SV exocytosis, dye molecules internalize during compensatory endocytosis and label newly formed SVs.
27
28 When labeled vesicles undergo exocytosis in dye-free medium, dye molecules dissociate from the plasma
29
30 membrane and lose fluorescence. To further support findings from electrophysiological studies showing
31
32 reduced SV release after *Dnm1* knockdown, FM1-47 was used to track SV recycling. Spinal cord slices
33
34 were incubated in Mg²⁺-free ACSF containing 4-aminopyridine (4-AP) to enhance calcium-dependent
35
36 neurotransmitter release. Tissues were incubated with FM1-43 for 3 min, washed and incubated with
37
38 ADVASEP-7 to scavenge unincorporated FM1-43. The dorsal roots were stimulated at 1 Hz 4-6V to
39
40 facilitate SV release from presynaptic terminals, which were imaged by fluorescence microscopy. After 1
41
42 Hz dorsal root stimulation, fluorescence at individual synapses declined in the CTR siRNA group,
43
44 representing exocytosis and consequent loss of labeled SVs. In contrast, synaptic fluorescence was
45
46 maintained in the *Dnm1* siRNA group (**Fig. 8H, I**).

47 48 49 ***Dnm1* siRNA inhibits spontaneous excitatory but not inhibitory events in the spinal cord**

50
51
52 No significant difference in the frequency of spontaneous synaptic events (total sPSC, including
53
54 sEPSCs and spontaneous inhibitory post-synaptic currents (sIPSCs) were observed between *Dnm1* and
55
56 CTR siRNA groups (**Fig. 8J, K**), which suggests the underlying network activity in the dorsal horn remains
57
58 functional after *Dnm1* knockdown. However, when the proportion of excitatory to inhibitory synaptic
59
60
61
62
63
64
65

1
2
3
4 events was compared by measuring sEPSC frequency in the presence of antagonists of GABA (gabazine)
5
6 and glycine (strychnine) receptors as a proportion of baseline sPSC frequency, there was a significant
7
8 reduction in the excitatory component in the Dnm1 siRNA group ($P=0.019$, Mann-Whitney test) (**Fig. 8L,**
9
10 **M**). This change is likely to be due to a reduction in spontaneous excitatory activity generated by primary
11
12 afferent neurons, while the spontaneous glycinergic and GABAergic events that originate from inhibitory
13
14 neurons in laminae II-III remain the same, leading to reduced nociceptive signaling.
15

16 17 **Dnm inhibition reduces the probability of SV release and prevents sustained release from presynaptic** 18 19 **primary afferent neurons**

20
21 To corroborate the findings with Dnm1 siRNA, we investigated the effect of the Dnm inhibitor
22
23 Dyngo4a on synaptic transmission. Dyngo4a (30 μM) reduced eEPSC amplitude in response to dorsal root
24
25 stimulation at increasing intensities compared to vehicle (DMSO/ACSF) (**Fig. 8N**). Dyngo4a reduced the
26
27 sustained neurotransmitter release when afferent inputs were stimulated with a 1 Hz train of impulses (**Fig.**
28
29 **8O, P**). There was a decrease in paired pulse ratio of eEPSCs in superficial dorsal horn neurons following
30
31 incubation in Dyngo4a, which suggests that presynaptic release is driving these changes in synaptic activity
32
33 (**Fig. 8Q**).
34
35

36 37 **AAK1 siRNA reduces the probability of SV release and prevents sustained release from presynaptic** 38 39 **primary afferent neurons**

40
41 We administered AAK1 or CTR siRNA to mice (i.t.) and recorded eEPSCs in response to
42
43 stimulation of the dorsal roots. The threshold voltage required to stimulate an eEPSC was higher in the
44
45 AAK1 siRNA group and current amplitudes were higher in the control group at lower stimulus strength
46
47 (**Fig. 9A**). AAK-1 siRNA also suppressed sustained neurotransmitter release when afferent inputs were
48
49 stimulated with a 1 Hz train (**Fig. 9B, C**).
50
51

52 53 **AAK1 inhibitors reduce the probability of SV release and prevent sustained release from presynaptic** 54 55 **primary afferent neurons**

56
57 The AAK1 inhibitors LP-935509 (1 μM) or SCG-AAK1-1 (100 nM) were bath-applied following
58
59 baseline recordings in the presence of the vehicle. Both compounds reduced eEPSC amplitude in response
60
61

1
2
3
4 to dorsal root stimulation at increasing intensities compared to baseline control (**Fig. 9D, E**), but the effects
5
6 were less significant than data from AAK-1 siRNA treated animals (**Fig. 9A**). When afferent inputs were
7
8 stimulated with a 1Hz train in the presence of these compounds, there was a significant reduction in
9
10 sustained release in the LP-935509 treated group compared to baseline control (**Fig. 9F**) but not in the SGC-
11
12 AAK1-1 group (**Fig. 9G**). The train of stimuli were limited to 8 pulses in these experiments to avoid
13
14 synaptic potentiation between the baseline control and drug treatment recordings. Paired pulse ratios were
15
16 not significantly different with either treatment (**Fig. 9H, I**).

17
18
19 Thus, Dnm1 and AAK1 siRNA and inhibitors deplete the readily releasable SV pool and suppress
20
21 SV release from presynaptic terminals, which disrupts neurotransmission in nociceptive circuits in the
22
23 spinal cord.
24

25 26 **Dnm1 siRNA reduces the number of SVs in spinal cord synapses**

27
28
29 Transmission electron microscopy was used to examine the effects of knockdown of *Dnm* mRNA
30
31 on SV recycling in the dorsal horn. A characteristic feature of synapses in mice treated with Dnm1 siRNA
32
33 was a reduction in the number of SVs and an increase in the proportion of clathrin-coated vesicular profiles
34
35 when compared to synapses in mice treated with CTR siRNA (**Fig. 10A-H**). Many of the coated profiles in
3
37 Dnm1 siRNA-treated mice appeared to be interconnected clathrin-coated buds (**Fig. 10E, F**). These results
38
39 are in line with the effects of Dnm1 deletion on the morphological appearance of synapses [29].
40
41

42 **Dnm siRNA attenuates activation of nociceptors**

43
44 In addition to inhibiting synaptic transmission, endocytosis inhibitors curtail signaling of GPCRs,
45
46 including protease-activated receptor-2 (PAR₂), in nociceptors and thereby blunt persistent nociception
47
48 [20]. To examine the role of Dnm in GPCR-evoked nociception, Dnm or CTR siRNA was administered
49
50 (i.t.) 48 h before injection of trypsin (10 μL, 80 nM i.pl.; PAR₂ agonist). In mice receiving CTR siRNA,
51
52 trypsin induced mechanical allodynia after 60 min (**Fig. 11A**). Dnm1+2+3 siRNA inhibited trypsin-evoked
53
54 allodynia. To ascertain whether these effects depend on disruption of trypsin-evoked sensitization of
55
56 nociceptors, we measured the rheobase (minimal input current to fire action potential) of small diameter
57
58 DRG neurons by patch-clamp recording. DRG were preincubated with trypsin (100 nM, 10 min), washed
59
60
61
62
63
64
65

1
2
3
4 and rheobase was measured 0 or 30 min later (**Fig. 11B**). In DRG from CTR siRNA mice, trypsin decreased
5
6 the rheobase at 0 and 30 min (control 79 ± 15 pA; 0 min 30 ± 4 pA, $P=0.002$ vs. control; 30 min 26 ± 4 pA,
7
8 $P=0.001$ vs. control, 1-way ANOVA, Dunnett's test, **Fig. 11C**). Dnm1+2+3 siRNA did not block the initial
9
10 effects of trypsin (control 72 ± 12 pA, 0 min 34 ± 5 pA, $P=0.003$ vs. control) but prevented the sustained
11
12 effects of trypsin (30 min, 68 ± 8 pA, $P=0.7$ vs. control, **Fig. 11D**). Thus, trypsin causes an immediate and a
13
14 sustained hyperexcitability of nociceptors; the sustained effect requires PAR₂ endosomal signaling.
15

16 17 18 19 20 **DISCUSSION**

21
22 We report a major role for Dnm and AAK1 in synaptic transmission within nociceptive circuits in
23
24 the dorsal horn of the spinal cord. *Dnm1*, *Dnm3* and *Aak1* mRNA were expressed in mouse and human
25
26 DRG, including in peptidergic nociceptors. Intrathecal siRNA or shRNA down-regulated *Dnm* and *Aak1*
27
28 mRNA in DRG neurons and reversed nociception in preclinical models of inflammatory and neuropathic
29
30 pain. Dnm, clathrin and AAK1 inhibitors replicated the effects of siRNA, supporting selectivity. Dnm1 and
31
32 AAK1 knockdown and inhibition blunted electrically-evoked synaptic transmission between primary
33
34 sensory neurons and dorsal horn neurons. These changes were coincident with the accumulation of SVs
35
36 within presynaptic nerve terminals. The results support the hypothesis that Dnm and AAK1 mediate the
37
38 endocytosis of SVs in nociceptive circuits and thereby sustain nociceptive transmission (**Fig. 12**).
39
40 Disruption of this process ameliorates pain.
41
42

43
44 The conclusion that Dnm mediates synaptic transmission in nociceptive spinal circuits is supported
45
46 by the expression of *Dnm1* and *Dnm3* mRNA in DRG and spinal cord neurons. *Dnm1* and *Dnm3* mRNA
47
48 were also expressed in human DRG neurons, providing translational relevance. Single-nucleus RNA
49
50 sequencing in mouse and human DRG tissue identified *Dnm1* and *Dnm3* in all sensory neuron subtypes
51
52 [25; 31]. *Dnm1* and *Dnm3* mRNA were coexpressed with CGRP in peptidergic nociceptors. Peptidergic
53
54 nociceptors are sensitized during pain and release neuropeptides that mediate pain transmission in the spinal
55
56 cord [2; 16]. However, Dnm isoforms were expressed by most primary sensory neurons as well as by
57
58 satellite glial cells, and thus participate in multiple processes. Intrathecal Dnm siRNA or shRNA down-
59
60
61
62
63
64
65

1
2
3
4 regulated *Dnm* mRNA in DRG neurons and reversed nociception in mice with persistent inflammatory and
5
6 neuropathic pain. Isoform-selective knockdown had anti-nociceptive actions, suggesting redundancy.
7
8 Differences in the magnitude of the antinociceptive actions of Dnm siRNA in models of inflammatory and
9
10 neuropathic pain could be attributable to different mechanisms of nociceptive transmission; further studies
11
12 are required to investigate this possibility. Simultaneous knockdown of all Dnm isoforms was more
13
14 efficacious and sustained than knockdown of individual isoforms, and also normalized behavioral changes
15
16 in a model of neuropathic pain. Dnm1 shRNA had large antinociceptive actions that were fully sustained
17
18 for at least 7 d in mouse models of inflammatory and neuropathic pain. A limitation of this study is that
19
20 knockdown was assessed at the level of mRNA rather than protein. Future studies will investigate the
21
22 correlation between the antinociceptive actions of shRNA and the degree of protein knockdown over time.
23
24

25
26 Electrophysiological studies support the conclusion that clathrin and Dnm sustain synaptic
27
28 transmission in nociceptive circuits by mediating the endocytosis and replenishing the releasable pool of
29
30 SVs of presynaptic terminals. Dnm1 knockdown and inhibition suppressed eEPSCs in superficial dorsal
31
32 horn neurons and depressed the paired pulse ratio of eEPSCs, which implicates a presynaptic mechanism
33
34 caused by a reduction in the probability of neurotransmitter release from primary afferent neurons. The
35
36 finding that Dnm1 siRNA disrupted the maintenance of eEPSCs during repetitive stimulation of dorsal
37
38 roots implicates Dnm in sustained synaptic transmission in nociceptive circuits. The imaging of SV
39
40 recycling with a styryl dye revealed that Dnm1 siRNA disrupts SV recycling, which would be secondary
41
42 to disruption of SV endocytosis. Ultrastructural studies showed that *Dnm1* mRNA knockdown reduced the
43
44 number of SVs and caused an accumulation of CCPs in presynaptic nerve terminals of dorsal horn synapses.
45
46
47
48 These morphological changes are consistent with the role of Dnm in SV endocytosis and are in accordance
49
50 with reported changes in SVs and CCPs in neurons cultured from *Dnm1* and *Dnm1+3* knockout mice [14;
51
52 29]. Thus, behavioral, electrophysiological and morphological studies support the conclusion that Dnm is
53
54 necessary for endocytosis of SVs in presynaptic nerve terminals in nociceptive circuits in the dorsal horn.
55
56
57 This process enables SV recycling, which is required for ongoing neurotransmission that underlies
58
59 nociceptive signaling within the spinal cord.
60
61
62
63
64
65

1
2
3
4 AAK1 participates in clathrin-mediated endocytosis [9; 32] and is a target for treatment of
5
6 neuropathic pain [21]. Anatomical, behavioral and electrophysiological studies support the hypothesis that
7
8 AAK1, like Dnm, mediates endocytosis of SVs in presynaptic neurons of nociceptive circuits in the dorsal
9
10 horn and is thus necessary for ongoing synaptic transmission of nociceptive signals. *Aak1* mRNA was
11
12 prominently expressed by primary sensory neurons of DRG, including peptidergic nociceptors, and in
13
14 neurons of the spinal cord. In line with these results, the α -subunit isoform of the AP2 complex, which it is
15
16 activated by the AAK1 phosphorylation, is preferentially expressed within CGRP+ve nociceptors [28].
17
18
19 Single-nucleus RNA sequencing studies demonstrated expression of *Aak1* in all DRG sensory neuron
20
21 subtypes of mouse and human [25; 31]. Intrathecal AAK1 siRNA downregulated the *Aak1* mRNA
22
23 expression in DRG neurons, reversed mechanical and thermal nociception in mice with inflammatory and
24
25 neuropathic pain, and suppressed electrically-evoked synaptic currents and neurotransmitter release from
26
27 presynaptic afferent neurons in the spinal cord. AAK1 shRNA had large and long-lasting antinociceptive
28
29 actions. The observations that two distinct inhibitors of AAK1 replicated the effects of AAK1 siRNA by
30
31 reversing nociceptive behavior and reducing the probability of SV release supports selectivity. These results
32
33 accord with genetic and pharmacological studies that revealed a major role of AAK1 in neuropathic pain
34
35 through global deletion or systemic antagonism of AAK1 [21]. The current research identifies an
36
37 anatomical site and mechanism of the pronociceptive actions of AAK1. The results support the hypothesis
38
39 that AAK1 mediates SV endocytosis in presynaptic terminals of nociceptors in the dorsal horn of the spinal
40
41 cord, which underlies SV recycling and sustained synaptic transmission of pain.
42
43
44

45
46 The observation that Dnm and AAK1 siRNA preferentially knockdown *Dnm* and *Aak1* mRNA in
47
48 DRG, rather than the spinal cord, supports the hypothesis that Dnm and AAK1 mediate pain transmission
49
50 by regulating presynaptic neurotransmission in the dorsal horn. The lack of discernable knockdown in the
51
52 spinal cord may be attributable to poor tissue penetration and targeting of neurons in deeper laminae that
53
54 are the main site of *Dnm* and *Aak1* mRNA expression. The current studies do not preclude an important
55
56 role for endocytosis in spinal neurons, which deserves further investigation.
57
58
59
60
61
62
63
64
65

1
2
3
4 In addition to mediating endocytosis of SVs in presynaptic nerve terminals, Dnm and AAK1 may
5
6 contribute to nociception by mediating endosomal signaling of pronociceptive GPCRs in primary afferent
7
8 neurons and spinal neurons (**Fig. 12**). Clathrin and Dnm mediate endocytosis of PAR₂ by nociceptors and
9
10 endocytosis of substance P and CGRP receptors by spinal neurons [18; 20; 40]. Endosomal signaling of
11
12 these GPCRs activates kinases that mediate sustained activation of neurons, which is necessary for
13
14 nociception. Accordingly, inhibitors of Dnm and lipid-conjugated or nanoparticle-encapsulated antagonists
15
16 that target GPCRs in endosomes have sustained anti-nociceptive effects [11; 18; 20; 22; 23; 40]. In the
17
18 current study, we observed that trypsin evokes mechanical allodynia in mice, which is known to be mediated
19
20 by PAR₂ [20]. Trypsin caused an immediate and a sustained increase in excitability of nociceptors.
21
22 Intrathecal Dnm1+2+3 siRNA inhibited mechanical allodynia and sustained hyperexcitability of
23
24 nociceptors. These results are in agreement with the effects of Dyngo4a on trypsin-evoked nociception [20].
25
26 These findings support the hypothesis that Dnm also contributes to nociception by mediating the endosomal
27
28 signaling of PAR₂ (and other GPCRs) that underlies neuronal hyperexcitability and pain.
29
30
31

32
33 *Is endocytosis in nociceptors a potential target for the treatment of pain?* An advantage is that
34
35 targeting endocytosis may surmount the redundancy of pain mechanisms. A plethora of mediators initiate
36
37 and maintain pain, which might explain the lack of efficacy of some highly selective inhibitors. A
38
39 disadvantage of targeting Dnm and AAK1 is their widespread distribution and multiple roles beyond pain.
40
41 We enhanced selectivity by administering siRNA, shRNA and antagonists into the intrathecal space, which
42
43 preferentially targeted DRG neurons. Notably, Dnm and AAK1 siRNA, shRNA and inhibitors did not affect
44
45 normal motor functions in mice with inflammatory or neuropathic pain, assessed by measuring withdrawal
46
47 responses of the contralateral paw. These treatments also did not affect multiple behaviors in sham-operated
48
49 mice, monitored using a behavioral spectrometer. Moreover, these treatments preferentially blocked
50
51 electrically evoked synaptic transmission, with no effects on basal synaptic transmission. The systemic
52
53 administration of Dnm inhibitors could disrupt essential cellular processes that depend upon endocytosis.
54
55 Indeed, deletion of Dnm 1 and Dnm3 is lethal in mice [14; 29]. However, global deletion of *Aak1* and
56
57 systemic administration of the AAK1 antagonist LP935509 inhibits nociception in mice and rats without
58
59
60
61
62
63
64
65

1
2
3
4 effects on normal motor function [21]. The AAK1 antagonist LX9211 was safe and well tolerated in healthy
5
6 subjects in phase 1 clinical trials [4]. The AAK1 inhibitor SGC-AAK1-1 shows improved selectivity over
7
8 the LX9211 [1]; to our knowledge its therapeutic potential has not been evaluated beyond the current study.
9
10 Another limitation is that we assessed nociception and did not evaluate the unpleasant emotional aspects of
11
12 pain, which requires assessment of affective responses to painful stimuli [12].
13
14

15
16 This study defined the contribution of Dnm and AAK1 to SV endocytosis in presynaptic terminals
17
18 of nociceptive circuits in the spinal cord, which is necessary for sustained transmission of nociceptive
19
20 signals. It also confirmed the contribution of endocytosis to GPCR-mediated sensitization of nociceptors.
21
22 Disruption of endocytosis and consequent inhibition of nociceptor sensitization and nociceptive
23
24 neurotransmission offers a non-opioid approach to treat pain.

FIGURE LEGENDS

Fig 1. Localization of *Dnm* mRNA in DRG and spinal cord. RNAScope® localization of *Dnm1*, *Dnm2* and *Dnm3* mRNA in DRG (A) and dorsal horn of the spinal cord (SC) (B) of mice. Arrows indicate mRNA expression within DRG and spinal cord neurons. Scale bar, 50 µm and in the detail box 20 µm. Representative images, n=5 mice per group. Quantification of expression of *Dnm1*, *Dnm2* and *Dnm3* mRNA in the DRG (C) and spinal cord (D) of mice determined by qRT-PCR, n=5 mice per group. RNAScope® localization of *Dnm1*, *Dnm2* and *Dnm3* mRNA in human DRG (E). Arrows indicate mRNA expression within DRG neurons. Scale bar, 50 µm. * Indicates fluorescent signal due to the presence of lipofuscin in human DRG neurons.

Fig 2. *Dnm* siRNA knockdown and inflammatory pain. RNAScope® localization (A) and quantification (number of dots per area) (B) of *Dnm1*, *Dnm2* and *Dnm3* mRNA expression in mouse DRG at 2 d after administration of *Dnm1*, *Dnm2*, *Dnm3* or control (CTR) siRNA, n=4 mice per group. Experimental timeline (C). Mechanical allodynia (D) and thermal hyperalgesia (E) induced by CFA measured 1 or 2 d after administration of *Dnm1*, *Dnm2*, *Dnm3* or CTR siRNA, n=8 mice per group. Mean±SEM. **P*<0.05,

52 d after administration of CTR siRNA (C) or *Dnm1*+2+3 siRNA (D). DRG neurons were challenged with
53
54 trypsin and washed. Rheobase was measured at T=0 and T=30 min following trypsin challenge. Numbers
55
56 in bars denote neurons measured. Mean \pm SEM. * P <0.05, ** P <0.01 vs. control or CTR siRNA. 2-way

5
6 D).

7
8 **Fig. 12. Hypothesized contributions of endocytosis in nociceptors to pain transmission.** The role of
9 endocytosis for GPCR signaling in the periphery and SV recycling centrally are depicted. At the peripheral
10 terminals of nociceptors, clathrin- and Dnm-mediated endocytosis of GPCRs, such as PAR₂, enables
11 sustained endosomal signaling that is necessary for activation of ion channels and ongoing central
12 transmission. At the central terminals of nociceptors, Dnm- and AAK1-mediated endocytosis of SVs
13 replenishes the releasable pool of SVs that is necessary for sustained synaptic transmission.

Pharmacological inhibitors and interfering RNAs targeting the key endocytic proteins dynamin and adaptor-associated kinase 1 prevent sensitization of nociceptors and block synaptic transmission of pain.
