20 **Abstract**

21 Recognition of extensional events of orogenic belts is critical for reconstructing convergent
22 orogenesis and its geodynamic evolution, but is also challenging due to multi-stage tectonic
23 superimposition. The South Tianshan is the southern margin of the Paleozoic Central Asian
24 Orogenic Belt (CAOB) and the key for understanding the geodynamic evolution of the CAOB.
25 Here we present new comprehensive structural, geochronological and geochemical data for the
26 Paleozoic sedimentary, igneous and metamorphic rocks in the Central and South Tianshan (NW
27 China). Based on our new results and published data, we suggest that a neritic to terrestrial back-
28 arc basin existed to the south of the Central Tianshan magmatic arc during the Early-Middle
29 Devonian. We document a crustal anatectic event (~304 Ma migmatization) associated with
30 peraluminous granitic magmatism (~305-295 Ma) in the South Tianshan. Multi-stage ductile
31 deformation events witnessed the Paleozoic evolution from subduction-accretion to post-orogenic
32 collapse of the Tianshan Orogen: (1) Late Devonian-Carboniferous regional top-to-the-north
33 ductile shearing is related to the southward subduction of the South Tianshan back-arc basin; (2)
34 late Carboniferous south-verging folds and brittle-ductile axial-plane cleavages correspond to
35 back-thrusting resulted from the collision between Central Tianshan and Tarim; (3) E-W-trending
36 ductile normal faults developed in migmatites are linked with syn-anatectic exhumation of the
37 middle crust during the latest Carboniferous post-collisional extension; and (4) regional dextral
38 strike-slip faulting attributed to Permian lateral extrusion. Therein, two stages of crustal extension
39 are key puzzle pieces to reconstruct the accretionary orogenic processes of the Paleozoic Tianshan.

40 **Keywords:** accretionary orogeny; migmatization; orogenic collapse; back-arc spreading;
41 extensional tectonics

1. Introduction

Extensional deformation is usually formed in settings such as horizontal tension, vertical magma upwelling, diapir/doming, and crustal thickening of orogens (Buck, 1991; Ruppel, 1995; Zhang & Huang, 2019). Traditionally, the study of orogenic belts has been led by convergence and compressional deformation, with relatively less consideration of orogenic evolution from an extensional perspective. In vast accretionary orogenic systems, passive margins and subduction-related back-arc spreading basins are the most typical and common large-scale extensional tectonics, opening avenues for understanding continental breakup, continent-ocean transition structures, and subduction switching (Faccenna et al., 2001; Heuret & Lallemand, 2005; Karner et al., 2007; Zhang & Huang, 2019). In addition, gravity-driven extension of thickened crust involving crustal melting and flow also plays a pivotal role in the evolution of orogens (Dewey, 1988; Rey et al., 2001). Crustal melting and flow is a key factor in the redistribution of component and heat within orogenic systems, the thickened and partial-melted (anatectic) crust in collisional orogens (e.g., Himalaya-Tibet Orogen) has attracted much attention (Beaumont et al., 2001; Block & Royden, 1990; Grujic et al., 1996; Jamieson et al., 2011), while little is known about crustal melting and flow in accretionary orogens (e.g., Lehmann et al., 2017). Unlike observable extensional tectonics in active subduction-accretion systems (e.g., the Circum-Pacific Belt), its identification in fossil orogens is challenging and requires tracing various geological clues, including deformation, metamorphism, magmatism and sedimentation. This study is on purpose to investigate how extensional tectonics anchor the geodynamic reconstruction of accretionary orogens through a case study of the Paleozoic Tianshan Orogen.

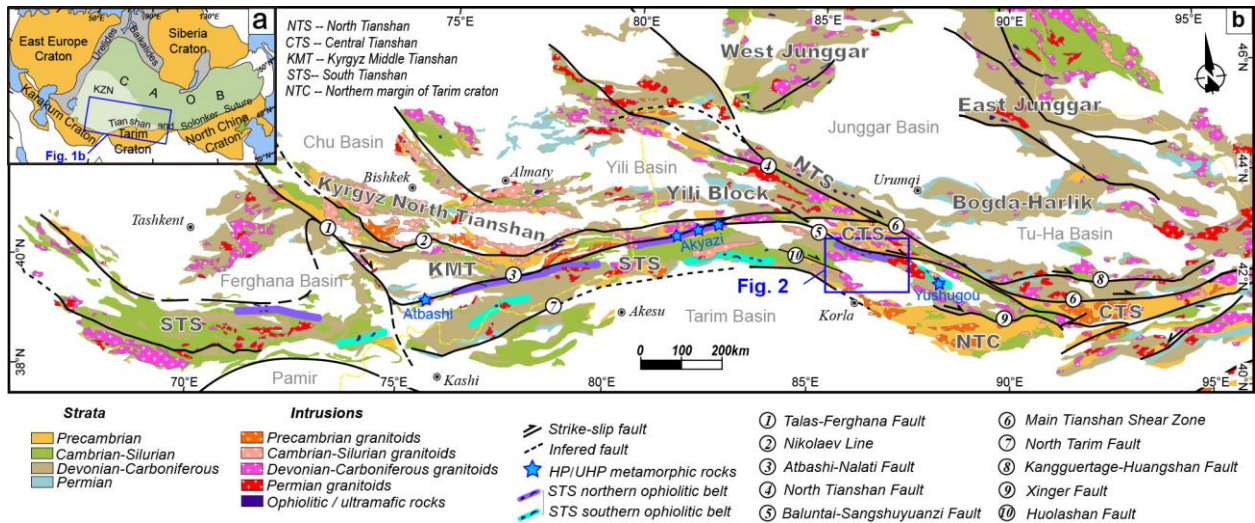

Fig. 1 (a) Tectonic position of the Central Asian Orogenic Belt (CAOB) (modified after Şengör et al., 1993). Abbreviation: KZN-Kazakhstan microcontinent. (b) Geological map of the Tianshan Orogen and adjacent regions (modified after XBGMR, 1993; Alexeiev et al., 2015).

The Tianshan Orogen is the southernmost part of the well-known Central Asian Orogenic Belt (Fig. 1a) (CAOB; or the Altaïds; Sengör et al., 1993; Windley et al., 2007), it was built by the subduction of the Paleo-Tianshan Ocean (PTO, also called Turkestan Ocean in Kyrgyz Tianshan; Safonova et al., 2016). Consumption of oceanic basins resulted in the amalgamation of the Kazakhstan microcontinent in the northwest with the Karakum-Tarim cratons in the south (e.g., Alexeiev et al., 2015; Charvet et al., 2011; Gao et al., 1998, 2009; Han et al., 2010, 2011; Han & Zhao, 2018; Liu et al., 2022; B. Wang et al., 2011b, 2018; X. S. Wang et al., 2022; Xiao et al., 2008, 2013; Zhong et al., 2019). So far, the dispute over the tectonic framework and geodynamic evolution of the Tianshan Orogen has focused on several scientific issues, including: (1) The nature of the PTO, it was considered as either a single broad oceanic basin (e.g., Gao et al., 1995b, 1995c, 1998, 2009; Long et al., 2011; Xiao et al., 2013); or alternatively, a SW Pacific-like archipelago arc-basin system (e.g., Charvet et al., 2007, 2011; Dong et al., 2005; Guo & Li, 1993; Loury et al., 2015; Shu et al., 2002; B. Wang et al., 2008, 2011b, 2018); (2) The timing of the final oceanic

9 83 (e.g., [Xiao et al., 2008, 2013](#); [Zhang et al., 2007](#)), or perhaps diachronous from east to west ([Chen](#)
10
11
12 84 [et al., 1999](#); [Loury et al., 2016](#)); (3) Various subduction polarities and kinematics were proposed
13
14 85 as well, e.g., north-directed (N-dipping) ([Chen et al., 1999](#); [Gao et al., 1995b, 1995c, 1998, 2009](#);
15
16 86 [Xiao et al., 2008, 2013](#)), south-directed ([Charvet et al., 2007, 2011](#); [Lei et al., 2011](#); [Lin et al.,](#)
17
18
19 87 [2009](#); [Loury et al., 2015](#); [Shu et al., 2002](#); [B. Wang et al., 2010, 2011b](#)) or bidirectional ([Gao et](#)
20
21 88 [al., 2009](#); [Ge et al., 2012, 2014](#); [Jiang et al., 2014](#)). Incomplete and limited records of Paleozoic
22
23
24 89 extensional tectonics in the Tianshan Orogen ([Liu et al., 2022](#)) partly raised above controversies
25
26 90 and obstructed our understanding of its tectonic evolution.
27

28
29 91 In this study, we present new structural data, zircon U-Pb ages and geochemical results of
30
31 92 Paleozoic magmatic and (meta-) sedimentary rocks in the Central-South Tianshan. Our data and
32
33 93 the newly recognized anatexis in the South Tianshan reveal two stages of tectonic extension within
34
35
36 94 different geodynamic backgrounds, and provide new constraints on the nature, timing of final
37
38 95 closure and subduction switching of the PTO. Integrating the previously published data, we
39
40
41 96 develop an evolutionary model for the PTO and Tianshan Orogen addressing the tectonic transition
42
43 97 from subduction-accretion, collision to post-orogenic collapse. Furthermore, our model provides
44
45
46 98 new insights into the crustal melting and flow of accretionary orogens in deep time of the earth.
47

48 99 49 50 100 **2. Geological setting**

51
52
53 101 The Tianshan Orogen extends over 2500 km from east to west across northwest China,
54
55 102 Kazakhstan, Kyrgyzstan, Tajikistan and Uzbekistan ([Fig. 1b](#)). In this study, we focus on the
56
57
58 103 western part of the Chinese segment of the Tianshan Orogen, which is tectonically divided into

104 the North Tianshan (NTS), Yili block (YB), Central Tianshan (CTS), and South Tianshan (STS)
105 (Fig. 1b). These tectonic units are separated by several suture zones, most of which have been
106 reworked by later strike-slip faults (Fig. 1b) (B. Wang et al., 2008, 2010).

107 The YB is separated from the NTS by the North Tianshan Fault to the north (Gao et al.,
108 1998; B. Wang et al., 2006, 2008), and from the CTS by the dextral strike-slip Nalati Fault to the
109 south (Fig. 1b) (Cao et al., 2017; Charvet et al., 2007, 2011; B. Wang et al., 2008, 2010). The
110 Meso- to Neoproterozoic metamorphic/crystalline basement of the YB is overlain by late
111 Neoproterozoic non-metamorphic limestones, tillites and siltstones, early-middle Paleozoic
112 carbonate, clastic rocks, and mid-late Paleozoic volcano-sedimentary sequences and arc-related
113 magmatic rocks related to the southward subduction of the Junggar - North Tianshan Ocean (Gao
114 et al., 1998; Han et al., 2010; Huang et al., 2016; Liu et al., 2014; Sun et al., 2021; B. Wang et al.,
115 2008, 2011a, 2014; Y. J. Wang et al., 2022; X. Y. Zhu et al., 2019, 2020).

116 The CTS is a continental block rifted away from the Tarim craton during the
117 Neoproterozoic (X. S. Wang et al., 2014, 2018) or early Paleozoic (Charvet et al., 2007, 2011; Guo
118 & Li, 1993; Shu et al., 2004, 2013; B. Wang et al., 2008, 2011b). It is composed of Proterozoic
119 gneiss, amphibolites and marbles basement rock assemblages, Silurian-Early Devonian
120 subduction-related granite-gneisses, and Ordovician-Silurian interlayered greenschist-facies meta-
121 sandstones and meta-volcanoclastic rocks (Alexeiev et al., 2015; Lei et al., 2011; Ma, Shu, Jahn,
122 et al., 2012; Ma, Shu, Santosh, et al., 2012; Shu et al., 2002, 2013; Shu, Deng, et al., 2011; B.
123 Wang et al., 2011b, 2018; X. S. Wang et al., 2017, 2020; Zhong et al., 2015). The early-middle
124 Paleozoic magmatic rocks developed in a continental arc, which was likely generated by the
125 subduction of the PTO (Charvet et al., 2007, 2011; Lei et al., 2011; Loury et al., 2015; Ma et al.,
126 2014; B. Wang et al., 2008; Zhong et al., 2015, 2019). Undeformed Late Devonian-Carboniferous

intrusions crosscut the early-middle Paleozoic arc-related rocks and their Precambrian basement, and display syn-/post-collisional geochemical features (Ma et al., 2014; Shi et al., 2007; Xu et al., 2014). Lower Carboniferous formations rest in angular unconformity upon deformed and metamorphosed lower Paleozoic rocks (Charvet et al., 2011; Gao et al., 1998; Shu et al., 2002; B. Wang et al., 2008, 2011b, 2018; XBGMR, 1993).

The STS is traditionally regarded as the area located between the Atbashi-Nalati-Baluntai Fault and North Tarim-Xinger Fault (Charvet et al., 2011; Gao et al., 1998, 2009, 2011; Ge et al., 2014; Han et al., 2011; Shu et al., 2002). The STS consists of Proterozoic basement beneath the Ordovician-Devonian continental arc (Alexeiev et al., 2015; Lin et al., 2013; Zhong et al., 2019), Cambrian-early Carboniferous marine sedimentary rocks (Alexeiev et al., 2015; Han et al., 2011; Shu et al., 2002; Xiao et al., 2013), and a series of ophiolitic mélanges associated with high- and ultrahigh-pressure (HP/UHP) metamorphic rocks (Gao et al., 1998; Gao and Klemd, 2003; Han et al., 2011; Jian et al., 2013; Jiang et al., 2014; 2015; Long et al., 2006; B. Wang et al., 2011b, 2018). There are two remarkable ophiolite mélanges exposed in the STS. The northern ophiolitic mélange belt is defined by the North Ferghana, Karaterek, Sartale, Kan, North Nuratau, Teskuduk, Bukantau and Atbashi mélanges developed in Uzbek and Kyrgyz Tianshan, and the Changawuzi, Dalubayi, Guluogou, and Wuwamen ophiolitic mélanges in Chinese Tianshan (Fig. 1b). Zircon U-Pb ages (448-332 Ma) of gabbros/basalts from the ophiolites and radiolarians/conodonts fossils in siliceous formations constrain these ophiolites as Ordovician to Carboniferous (Alexeiev et al., 2015, 2016; Dolgoplova et al., 2017; Jiang et al., 2014; Mirkamalov et al., 2012; X. S. Wang et al., 2018). The ophiolitic mafic rocks belong to MORB (mid-ocean-ridge basalt) and OIB (ocean-island basalt), except the Guluogou-Wuwamen ophiolites showing SSZ-type (supra-subduction zone) characteristics (Dong et al., 2005; Gao et al., 1995b, 1995c; Jiang et al., 2014; Long et al.,

2006; B. Wang et al., 2011b, 2018). In addition, a HP/UHP metamorphic complex is exposed in the Akyazi-Kekesu areas, to the south of the Nalati fault (Gao et al., 1995a; 2000; Gao and Klemd, 2003; Klemd et al., 2015; Lin et al., 2009; B. Wang et al., 2010; Wei et al., 2003; Zhang et al., 2007), and extends westward into the Atbashi area in Kyrgyzstan (Hegner et al., 2010; Loury et al., 2015, 2016). The peak metamorphism occurred during ca. 345-320 Ma, and then experienced retrogression during ca. 330-305 Ma (Gao & Klemd, 2003; Hegner et al., 2010; Klemd et al., 2005, 2011; Li et al., 2011; B. Wang et al., 2010; L. J. Zhang et al., 2018).

The southern ophiolitic belt consists of Jigen, Qiqijianake, Heiyinshan, Misibulake, Aertengkesi, Madaleke, Kulehu, Serikeyayilake, Yushugou and Tonghuashan ophiolitic mélanges from west to east (Fig. 1b). These ophiolites have been dated at 440 Ma to 392 Ma by zircon U-Pb ages or microfossils (Charvet et al., 2007, 2011; Han et al., 2011; Long et al., 2006; B. Wang et al., 2010, 2011b, 2018). Geochemical and structural studies indicate that these ophiolitic mélanges were formed in a back-arc setting and were tectonically emplaced from the south to the north (Charvet et al., 2007; Dong et al., 2005; Gao et al., 1998; Long et al., 2006; Shu et al., 2004; B. Wang et al., 2011b). Additionally, Jian et al. (2013) considered the Yushugou ophiolitic mélange and associated high-pressure granulites as a result of mantle diapirism in a continental back-arc (i.e., extensional) setting.

The northern margin of the Tarim craton is composed of Archean to Neoproterozoic basement rocks developed mainly in the Kuluketag (Hu et al., 2000; Long et al., 2011; Shu et al., 2013; Shu, Deng, et al., 2011; XBGMR, 1993; Zhu et al., 2011) and Akesu areas (Wu et al., 2022), gently folded late Cambrian-Early Ordovician limestone, marls and phosphate rocks, which suggest a passive margin setting (Chen et al., 2009; Han et al., 2015; XBGMR, 1993), and late

1
2
3
4 172 Silurian-Devonian arc-related magmatic rocks (Ge et al., 2012, 2014; Lin et al., 2013; Zhong et
5

180 al. (2008).

181 182 3. Field geology and structural features

183 In this study, we present field and microscopic structural data mainly from two
184 representative sections: the Kerguty section located to the north of Heshuo City (Fig. 2 and 3), and
185 the Chahan-Wusu section situated to the middle reaches of the Kaidu River (Fig. 2 and 6a). In both
186 sections rich records of Paleozoic magmatism, multi-stage deformation and metamorphism are

1
2
3
4 187 well preserved, but few data were previously reported. The structural patterns and phases of
5
6 188 different deformation events are highly variable depending on lithology and age. Hereafter we use
7
8
9 189 index symbols such as D_{K_n-i} and D_{Ch_n-i} to represent the different phases of deformation, where
10
11
12 190 capitalized subscripts K and Ch correspond to the Kerguty and Chahan-Wusu sections,
13
14 191 respectively; italic subscript n (=1 to 3) stands for the litho-tectonic unit, and lowercase i (=1 to 3)
15
16 192 denotes the phases of deformation (Table 1).

19 193 **3.1 Kerguty Section**

20
21 194 This section can be divided into three units based on lithological, metamorphic and
22
23
24 195 deformation features (Fig. 3b). From south to north, Unit 1 is represented by sedimentary
25
26 196 sequences with brittle-ductile deformation, Unit 2 consists of migmatitic metasedimentary rocks,
27
28
29 197 and Unit 3 is mainly composed of deformed granitoids (Fig. 3b and Table 1).

30
31 198 The Unit 1 is characterized by Devonian deformed alternating limestone and sandstone
32
33 199 (Fig. 3b). The dominant deformation structures are a series of south-verging tight folds with
34
35
36 200 steeply NNW-dipping axial slaty cleavage or schistosity (Fig. 3b, 4a and 4b). From the south to
37
38 201 the north, the primary beddings were gradually transposed into foliations (Fig. 3b), indicating
39
40
41 202 increasing deformation intensity. The asymmetric folds and axial-parallel cleavage/schistosity
42
43 203 indicate a top-to-the-south thrusting, which is labeled as D_{KI-2} . Notably, B-type sub-horizontal
44
45 204 penetrative stretching lineation occurred in the core of the folds, which is likely due to the
46
47
48 205 interlayer slip related to the NW-SE shortening (Fig. 3b). In contrast, in limestone only, the
49
50
51 206 mylonitic foliation is refolded by “Z-type” asymmetric micro-folds on both limbs of the D_{KI-2} folds
52
53 207 (Fig. 3b and 4a), and consistently indicate a top-to-the-north shearing (Fig. 4a). As this structure
54
55 208 was developed in more ductilely deformed rocks and overprinted by the D_{KI-2} south-verging
56
57
58 209 folding, it most likely represents an earlier deformation event (i.e., D_{KI-1}). In the northern part of

210 Unit 1, sedimentary rocks were all ductilely deformed, and the deformed limestones contain
211 lensoid granite dykes and quartz veins. These lenses are enveloped by the foliations (Fig. 3b and
212 4b), thus suggesting that the dykes intruded before D_{K1-1} . Some sigmoid quartz veins (Fig. 4b)
213 show a top-to-the-north shearing sense, which should represent the D_{K1-1} kinematics. In the
214 northernmost part of Unit 1, an undeformed porphyritic coarse-grained biotite K-feldspar granite
215 with dark enclaves intruded in the deformed metasediments (Fig. 3b and 4c). Finally, numerous
216 north-dipping reverse faults crosscut the D_{K1-1} folds and separate the ductile and brittle deformation
217 domains; due to their structural level and pattern and top-to-the-south kinematics, these faults may
218 be related to D_{K1-2} (Fig. 3b).

219 The Unit 2 is separated from the Unit 1 by a north-dipping reverse fault (Fig. 3b), and its
220 northern boundary is the Baluntai fault (Fig. 3). This unit is composed of biotite gneiss, migmatite,
221 amphibolite, mica schist, and garnet-bearing leucogranite dykes that often crosscut the foliations
222 in metamorphic rocks (Fig. 3b and 4d-h). We distinguished two stages of ductile deformation in
223 this unit. The first deformation (D_{K2-1}) is characterized by penetrative foliation and associated dip-
224 slip to oblique stretching lineation, marked by elongated mica aggregates and stretched quartz and
225 feldspar ribbons (Fig. 3b and 4g). Migmatite-gneisses crop out mostly in the northern part of this
226 unit (Fig. 3b and 4e) with asymmetrically folded quartzo-feldspathic veins, suggesting a top-to-
227 the-north or to the NW syn-migmatitic shearing (Fig. 4f). On thin sections cut perpendicular to
228 foliation and parallel to lineation, oblique relationship between the gneissic foliation and quartz
229 grain boundaries formed by subgrain rotation recrystallization (SGR) suggest a top-to-the-NW
230 normal shearing (Fig. 4h). In the middle part of the migmatite unit, foliations and folds are usually
231 irregular but mostly become gentle and nearly flat (Fig. 3b). In the southern part, a series of
232 asymmetric folds with sub-horizontal hinges suggest southward normal shearing (Fig. 4i). Such

233 overall deformation fabrics and kinematics indicate a dome-like structure of the migmatitic unit
234 (Fig. 3a), although the eastern and western sides of the inferred dome could not be investigated
235 due to their inaccessibility. These structures are considered to represent a single deformation event
236 marked as D_{K2-1} . The second deformation (D_{K2-2}) is characterized by sub-vertical ~NW-SE-
237 striking mylonitic foliation developed close to the Baluntai Fault, accompanied by well-developed
238 sub-horizontal stretching lineation and A-type folds (Fig. 4j). Outcrop-scale S-C fabrics indicate a
239 dextral sense of shearing (Fig. 4k). The superimposition of D_{K2-2} on the earlier D_{K2-1} event can
240 only be locally recognized, and the overprint effect decreases with distance away from the Baluntai
241 Fault. Furthermore, the brittle reverse faults (D_{K2-3}) also develop in this unit and crosscut both the
242 D_{K2-1} and D_{K2-2} structures (Fig. 3b).

243 The Unit 3 develops to the north of the Baluntai Fault (Fig. 3) and is dominated by ductilely
244 deformed early Paleozoic granodiorites (Fig. 3b and 5a) which extend to the Baluntai area and
245 occupy a large surface of southern Central Tianshan block (Fig. 2). In the granodiorites relatively
246 far away from the Baluntai Fault, the gneissic foliation gently dips to the SSW (Fig. 5b) with
247 moderately developed down-dip stretching lineation (D_{K3-1}), and asymmetric fabrics indicate a
248 top-to-the-north shearing (Fig. 3b). Close to the Baluntai Fault, dioritic/granitic rocks show E-W-
249 striking sub-vertical mylonitic foliations bearing sub-horizontal stretching lineation, mostly
250 formed during the Permian dextral strike-slip motion of the Baluntai Fault (D_{K3-2}) (Fig. 3b and 5d)
251 (B. Wang et al., 2009; Yin et al., 1998; Zhong et al., 2015). On some outcrops, paragneiss,
252 micaschist and meta-sandstone are in fault contact with the granodiorite. The foliations in these
253 meta-sedimentary rocks are inconsistent with those of the granodiorite, probably due to localized
254 rotation along the faults. A series of undeformed E-W-striking K-feldspar granite dykes crosscut
255 both the granodiorite and meta-sedimentary rocks (Fig. 3b, 5a and 5c).

3.2 Chahan-Wusu Section

284 The Chahan-Wusu section is ~2 km long and located ~100 km to the west of the Hejing
285 County (Fig. 2 and 6a). The northern part of this section consists of Carboniferous undeformed
286 granites (Fig. 2, 6a and 6b) that thrust southward upon the Carboniferous massive limestone of
287 >200m thick (Fig. 6b and c). The limestone is in fault contact with the Middle Devonian
288 volcanoclastic sequences of the Sa'erming Group, which consists of andesitic tuff, tuffite,
289 tuffaceous greywacke, mudstone, and siltstone (Fig. 6a). The southern part of the Sa'erming Group
290 is mainly composed of alternating gray-green sandstone and purple mudstone showing ripple
291 marks and cross-beddings (Fig. 6a and d-f), indicating a shallow-water deposition environment. In

292 the Devonian sequences, cleavage and/or schistosity are well developed; the relationship between
293 cleavage and bedding, as well as cross-bedding, graded-bedding and asymmetric ripples in the
294 clastic rocks, all suggest a normal stratigraphic sequence and an overall paleocurrent direction
295 from the south to the north (Fig. 6a and d-g).

296 Three stages of deformation can be recognized in the Chahan-Wusu section and its vicinity.
297 The dominant deformation structure (denoted as D_{Ch-1}) is characterized by a series of cleavage or
298 schistosity (S1) (Fig. 6a) that are oblique to the sedimentary bedding (S0) and steeply dipping to
299 NNE without obvious stretching lineation. The intensity of the deformation is highly depending
300 on lithology, and mostly concentrated in the weak siltstone and mudstone layers. Geometric
301 relationship between the bedding and schistosity/cleavage implies south-verging asymmetric
302 folding. The second stage of deformation (D_{Ch-2}) can be recognized only in the southwest extension
303 of the section and represented by a series of dextral strike-slip faults (Fig. 2). In the deformed
304 greenish tuffaceous siltstone, crenulation (B-type lineation) occurs on sub-vertical schistosity
305 surfaces and shows oblique-slip patterns plunging towards the west (Fig. 6h). At the microscopic
306 scale, occasionally visible σ -type quartz lenses indicate dextral kinematics on the XZ plane
307 perpendicular to both the schistosity and the crenulation hinge (Fig. 6i). Thus, this deformation
308 was likely caused by dextral strike-slip shearing along the northern Huolashan Fault zone (Fig. 2)
309 (Lin et al., 2013).

310 It is noteworthy that the above-mentioned south-verging thrust faults bordering and cutting
311 into different lithological units may have formed synchronously with the D_{Ch-1} asymmetric folds
312 as suggested by their similar stress field; however, these faults were apparently reactivated during
313 the Cenozoic episodic uplift recorded by the development of multiple perched terraces along the

314 Chahan-Wusu River (supplementary Fig. S1). Thus, this brittle south-verging thrusting (D_{Ch-3}) can
315 also be related to the Cenozoic N-S shortening and tectonic reactivation (Jolivet et al., 2010).

327 4. Sampling and analytical results

328 4.1 Sampling

329 In order to constrain the ages of deposition, ductile deformation and migmatization of the
330 meta-sedimentary and meta-igneous rocks in the Kerguty section, we collected four granitoids
331 (12TS74, 12TS73-2, 12TS77-2 and 12TS98), three clastic rocks (12TS73-1, 12TS82-1 and
332 12TS93-1) and three migmatite samples (12TS95, 12TS82-3 and 12TS80-2) for laser-ablation
333 inductively coupled plasma mass spectrometry (LA-ICP-MS) zircon U-Pb dating (Fig. 3a and 3b).
334 Sample 12TS74 is a deformed granodiorite from the north of the Baluntai Fault, sample 12TS73-
335 2 is a foliated K-feldspar granite dyke intruded into granodiorite (Fig. 3b and 5a), and sample
336 12TS77-2 was taken from a mylonitic granite close to the Baluntai Fault (Fig. 3b and 5d). In the
337 granodiorite, minor hornblende co-exists with quartz (Fig. 5e). These deformed granitoids show
338 subgrain rotation (SGR) and grain boundary migration (GBM) recrystallization of quartz (Fig. 5f),
339 indicating middle- to high-temperature deformation. Sample 12TS98 was collected from the
340 undeformed biotite K-feldspar granite intruding the schistose metasedimentary rocks (Fig. 3b and
341 4c). Sample 12TS73-1 was taken from the meta-sandstone in fault contact with the foliated
342 granodiorites (Fig. 3b and 5c). Samples 12TS93-1 and 12TS82-1 are paragneiss (metatexites) from
343 the migmatite unit (Fig. 3b). Leucogranite (12TS95), leucosome (12TS82-3) and diatexite
344 (12TS80-2) were sampled to constrain the time of the migmatization (Fig. 3b and 4d-f).
345 Furthermore, one sample of leucosome (12TS82-3), two deformed granodiorite samples (12TS72-
346 1, 12TS72-2) and two undeformed granite samples (12TS98, 12TS99) were selected for whole-
347 rock geochemical analysis (Fig. 3a and b).

348 From the Chahan-Wusu section and its adjacent areas, one andesitic tuff (12TS62-3) and
349 three clastic samples (12TS68-2, 12TS69-1, 12TS62-1) were collected for LA-ICP-MS zircon U-

1
2
3
4 350 Pb dating. These volcanoclastic rocks display tuffaceous texture, consisting of subhedral-anhedral
5
6 351 plagioclase, quartz, minor hornblende crystal fragments, in a volcanic dust matrix (Fig. 6j and k).
7
8
9 352 In addition, five andesitic tuff samples (12TS62-2, 12TS62-3, 12TS66-1, 12TS66-2 and 12TS68-
10
11 353 1) and two tuffaceous greywacke samples (12TS67-1, 12TS67-2) were chosen for whole-rock
12
13
14 354 geochemical analysis. The specific locations of the samples are shown in Fig. 2, 6a and in
15
16 355 supplementary Table S1, S2.

19 356 **4.2 Zircon U-Pb Ages**

21 357 The results of LA-ICP-MS zircon U-Pb dating are presented in the supplementary Table
22
23
24 358 S1 and S2. The analytical procedures and cathodoluminescence (CL) images (Fig. S2-S5) of all
25
26 359 analyzed zircons are shown in the supporting information file.

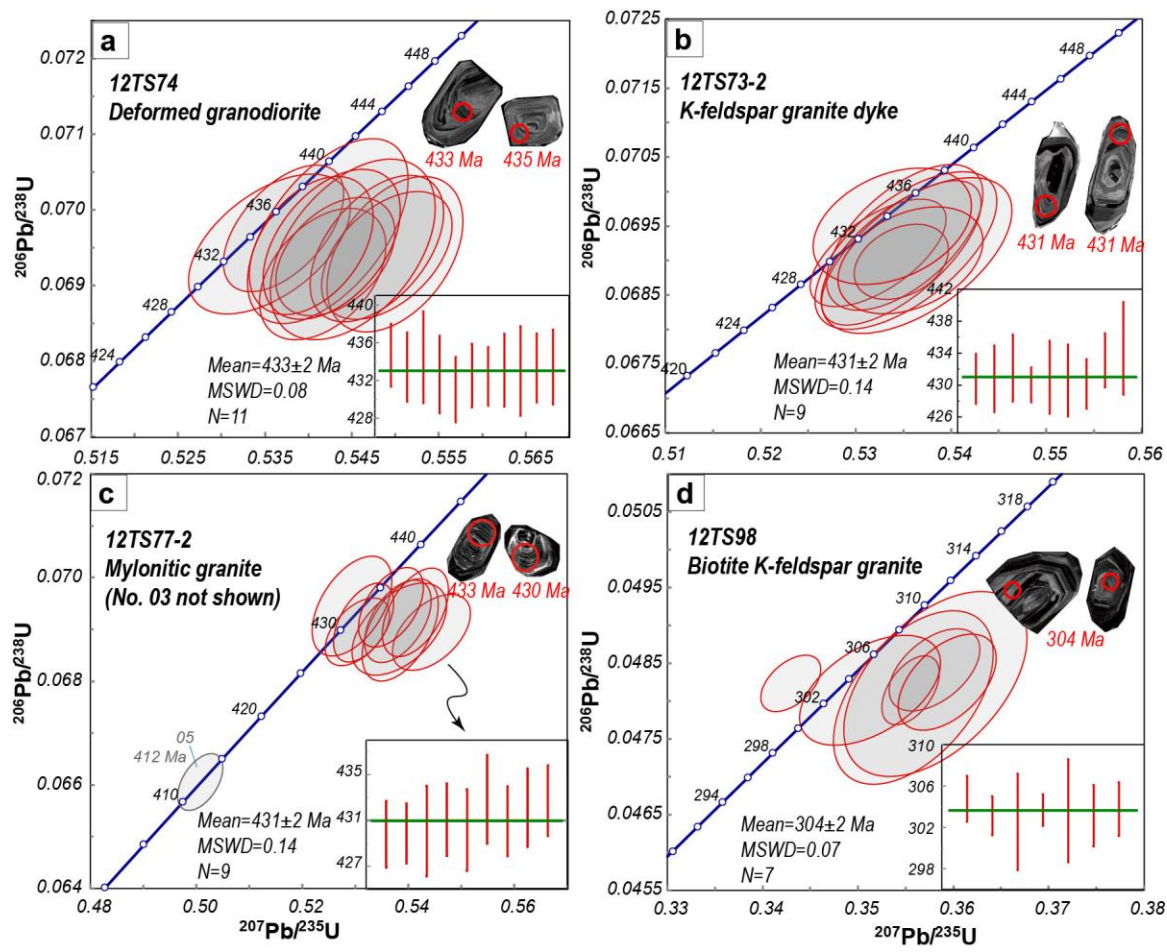

29 360 **4.2.1 Granitoids of the Kerguty section**

31 361 Zircons from the foliated granodiorite sample 12TS74 are euhedral with length/width ratios
32
33 362 of 1 to 4, and display bright and dense concentric oscillatory zoning in the CL images (Fig. S2),
34
35
36 363 indicative of magmatic origin. A few of zircons exhibit irregular zoning and narrow bright rims
37
38 364 (No. 11 in Fig. S2), which may be caused by later fluid alteration. After eliminating six discordant
39
40
41 365 ages, eleven grains with consistent $^{206}\text{Pb}/^{238}\text{U}$ apparent ages around 430 Ma define a weighted
42
43 366 mean age of 433 ± 2 Ma (MSWD=0.08, Th/U=0.42-0.82) (Fig. 7a and Table S1), which is
44
45 367 interpreted as the crystallization age of the granodiorite.

48 368 The texture and crystal morphology of zircons in the foliated K-feldspar granite sample
49
50 369 12TS73-2 are similar to those of the host granodiorite sample 12TS74 (Fig. S2), but showing more
51
52
53 370 developed overgrown rims, which are, however, not wide enough to date. A weighted mean age
54
55 371 of 431 ± 2 Ma (MSWD=0.14, Th/U=0.46-0.78) (Fig. 7b and Table S1) is calculated from nine
56
57
58 372 concordant analyses; this age is consistent with the age of the host granodiorite 12TS74 within

373 errors. These zircons were likely derived from the host granodiorites. Additional six grains yielded
374 discordant results likely from Pb loss during subsequent events.

375
376 **Fig. 7** Zircon U-Pb Concordia diagrams and representative zircons CL images for granitoids of the Kerguty
377 section. The CL images of all dated zircons are shown in supplementary Fig. S2.

379 From the mylonitic granite sample 12TS77-2 close to the Baluntai fault, euhedral-
380 subhedral zircons show grey concentric oscillatory zoning (Fig. S2). A few of grains show small
381 inherited cores (No. 12 and 21) and inclusions (No. 14 and 20), which may have affected the
382 analytical results yielding discordant ages (Fig. S2). One zircon grain No. 03 shows grey and
383 diffuse zoned core and yielded a Proterozoic age that is interpreted as inheritance of older basement
384 (Fig. S2 and Table S1). Nine concordant analyses yielded apparent $^{206}\text{Pb}/^{238}\text{U}$ ages clustering

2
3
4 385 around 430 Ma and the weighted mean age of 431 ± 2 Ma (MSWD=0.14, Th/U=0.17-0.70) (Fig.
5
6 386 7c and Table S1) is interpreted as the crystallization age of the mylonitic granite. Additionally,
7
8
9 387 zircon No. 05 with a younger age of 412 Ma and low Th/U ratio of 0.26 (Fig. 7c and Table S1),
10
11 388 may imply influence of later deformation-induced reworking. The rest 10 zircon grains are
12
13
14 389 discordant (Fig. S2 and Table S1).

15
16 390 Zircon from the undeformed biotite K-feldspar granite (12TS98) are large (100-300 μm)
17
18
19 391 and euhedral with length/width ratios ranging from 1.5 to 3, they show dense and bright oscillatory
20
21 392 zoning, similar to typical felsic magmatic zircons (Fig. S2 and Table S1). Seven out of all eleven
22
23
24 393 analyses yielded concordant ages around 300 Ma, and a weighted mean age of 304 ± 2 Ma
25
26 394 (MSWD=0.07, Th/U=0.08-1.71) (Fig. 7d and Table S1) is considered as the crystallization age of
27
28
29 395 the biotite K-feldspar granite.

30 31 396 4.2.2 Migmatites of the Kerguty section

32
33 397 Twenty zircons were dated for the leucogranitic dyke sample 12TS95, most zircons are
34
35
36 398 euhedral to subhedral and show dark CL images with weak or no oscillatory zoning, except two
37
38 399 grains with bright CL images (No. 08 and 14) (Fig. S3 and Table S1). Thirteen analyses yielded
39
40
41 400 concordant $^{206}\text{Pb}/^{238}\text{U}$ apparent ages clustering around 300 Ma with a Concordia age of 304 ± 2 Ma
42
43 401 (MSWD=3.5, Th/U=0.01-0.23) (Fig. 8a and Table S1). Two older ages of ~ 490 Ma for the bright
44
45
46 402 zircon grains are interpreted as inheritance. Only one zircon grain No. 09 has a young apparent
47
48 403 age of ~ 261 Ma and a high Th/U ratio of 3.70 (Fig. 8a and Table S1), its origin and significance
49
50
51 404 are unclear. The rest of four dark zircons yielded discordant results and were excluded from further
52
53 405 discussion.

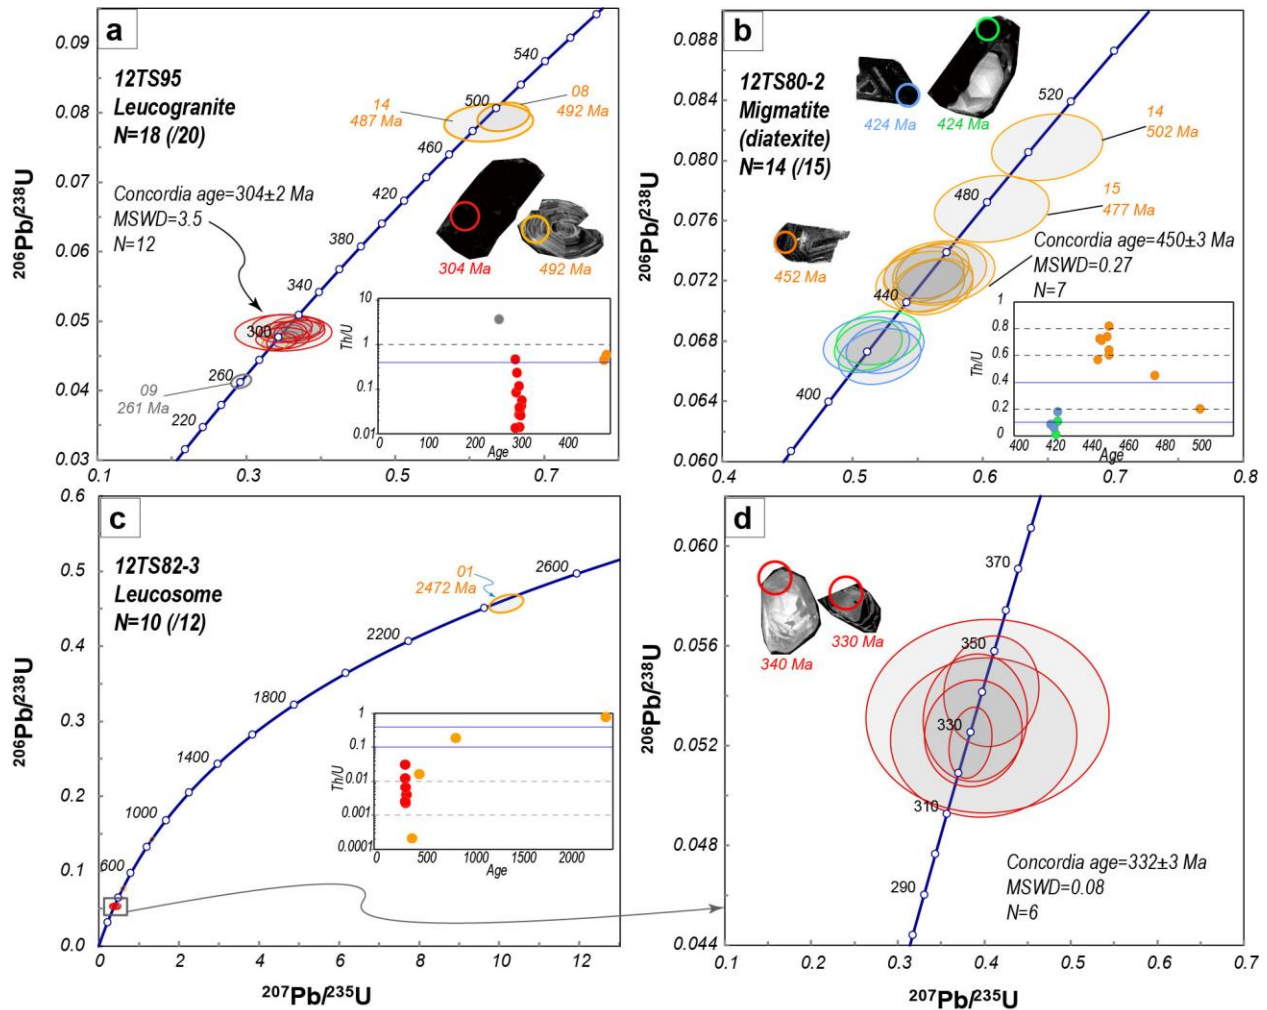

Fig. 8 Zircon U-Pb Concordia diagrams, representative zircons CL images, and Th/U ratios vs. U-Pb age plots (insets) for migmatites of the Kerguty section. The CL images of all dated zircons are shown in supplementary Fig. S3.

From the migmatite (diatexite) sample 12TS80-2, most zircons are euhedral-subhedral, they show dark CL images and grey concentric oscillatory zoning, suggesting a magmatic origin; while a few of grains show unclear oscillatory zoning or have complex internal textures (Fig. S3), indicative of hydrothermal or metamorphic overprints. Five zircons show relatively black CL images, two analyses on overgrown rims and three on dark oscillatory zoning (Fig. S3) have low Th/U ratios ranging from 0.01 to 0.18 (Fig. 8b and S3), and the meaning of their younger ages

417 (~420 Ma) will be further discussed in the next chapter. The rest of nine concordant analyses
418 yielded older $^{206}\text{Pb}/^{238}\text{U}$ apparent ages ranging from 502 to 446 Ma, seven of them cluster around
419 450 Ma with a Concordia age of 450 ± 3 Ma (MSWD = 0.27). These older ages are interpreted as
420 inherited zircons (Fig. 8b and Table S1).

421 Zircons from the leucosome sample 12TS82-3 are variable in size, most of them have
422 anhedral shapes and bright CL images with unclear or irregular zoning (except a dark grain No.
423 03). They develop thin and dark overgrown rims (Fig. S3) indicating later metamorphic or thermal-
424 fluid assisted growth, but these rims are too narrow to date. Six analyses on the bright zircon cores
425 yielded concordant $^{206}\text{Pb}/^{238}\text{U}$ apparent ages clustering around 330 Ma, and their Concordia age is
426 calculated as 332 ± 3 Ma (MSWD=0.08) (Fig. 8c and Table S1). The remaining four concordant
427 analyses provide older apparent ages ranging from 2427 to 399 Ma (Fig. 8c-d and Table S1), which
428 are interpreted as inheritance from the melted parent clastic rocks containing Precambrian and
429 Paleozoic detritus.

4.2.3 Meta-sedimentary rocks in the Kerguty section

431 From the meta-sandstone sample (12TS73-1) and paragneiss samples (12TS82-1, 12TS93-
432 1), most zircons are euhedral or subhedral, and display clear oscillatory zoning, indicative of
433 magmatic origin. A few of zircons from each sample show irregular shapes and complex internal
434 textures with sector and homogeneous zoning and inherited cores (Fig. S4). These detrital zircons
435 generally show high Th/U ratios with few exceptions lower than 0.1 (Table S2), which might have
436 been changed by later metamorphic or fluid overprints. After eliminating discordant analyses (15%
437 of dated grains), majority detrital zircon ages (85% of analyses) for each of three meta-sedimentary
438 rocks define similar zircon populations showing a single major age peak at 435 Ma for sample
439 12TS73-1, 421 Ma for 12TS82-1 and 444 Ma for 12TS93-1 (Fig. 9). Only one zircon (No. 06)

440 from sample 12TS73-1 yielded a younger age at ~311 Ma (Fig. 9a and b), which probably resulted
 441 from metamorphism but its geological meaning remains unclear on such a single exception. From
 442 these three samples, about 7% to 49% of dated concordant zircons yielded Precambrian ages,
 443 distributing in ranges of 650-750 Ma, 800-1000 Ma, 1200-1500 Ma, 1700-2000 Ma and 2400-
 444 2500 Ma (Fig. 9).

445 **Fig. 9** Zircon U-Pb Concordia diagrams (a, c and e), relative density curves and histograms (b, d and f),
 446 and Th/U ratios vs. U-Pb age plots (insets of b, d and f) for clastic rocks of the Kerguty section. The CL
 447 images of all dated zircons are shown in supplementary Fig. S4.
 448

4.2.4 Volcanoclastic rocks from the Chahan-Wusu section

Zircons from the andesitic tuff sample 12TS62-3 are mostly euhedral-subhedral with length/width ratios of 1-2, and display clear oscillatory zoning with high Th/U ratios (0.24-1.49) (Fig. 10a and b), suggesting a magmatic origin. Thirty-three concordant analyses yielded apparent $^{206}\text{Pb}/^{238}\text{U}$ ages from 940 to 391 Ma (Fig. 10a and Table S1), therein, two Proterozoic ages obtained from a dark core and a bright mantle (zircons No. 07 and 29) (Fig. S5 and Table S1) are interpreted as inheritance of Precambrian basement; seventeen zircons have $^{206}\text{Pb}/^{238}\text{U}$ apparent ages of ~420 Ma and define a mean age of 419 ± 1 Ma (MSWD=0.15) (Fig. 10b) that is considered as the eruption age of the andesitic tuff. Thirteen grains yielded ages ranging from 493 to 434 Ma, and eight of them cluster at ~435 Ma with a weighted mean age of 435 ± 2 Ma (MSWD=0.14) (Fig. 10b), all of them are interpreted as detrital zircons derived from earlier magmatism. One zircon (No. 23) with an exceptional younger age (391 Ma, Th/U=0.39) was excluded for interpretation as its geological meaning is unclear. The other 17 zircons yielded discordant ages (Fig. 10b and Table S1).

Zircons from one weakly deformed tuffaceous lava (12TS68-2) and two schistose tuffaceous sandstones (12TS69-1 and 12TS62-1) (Fig. 6) show prismatic shapes and variable sizes, most of them demonstrate concentric or banded oscillatory zoning in their CL images (Fig. S5), which implies magmatic origin. After eliminating discordant zircons, the remaining grains have Th/U ratios mostly higher than 0.4 with a few in the range of ~0.1-0.4 (Fig. 10d, f, h and Table S2). Age spectrum of tuffaceous lava sample 12TS68-2 is characterized by a predominant peak at 409 Ma defined by 71% of the total analyses (Fig. 10c and d). This sample also contains a few of Precambrian grains with ages of ~768 Ma, ~940 Ma and ~1820 Ma (Fig. 10d). Zircon age spectra of tuffaceous sandstones (12TS69-1 and 12TS62-1) similarly show major Paleozoic age peaks at ~448 Ma and ~420 Ma, respectively (Fig. 10f and h). The proportions of Precambrian zircons in

these two tuffaceous sandstones increase up to 32-63%, and show wide age ranges spanning in 750-1000 Ma, 1100-1200 Ma, 1300-1500 Ma and 2400-2700 Ma intervals (Fig. 10e-h).

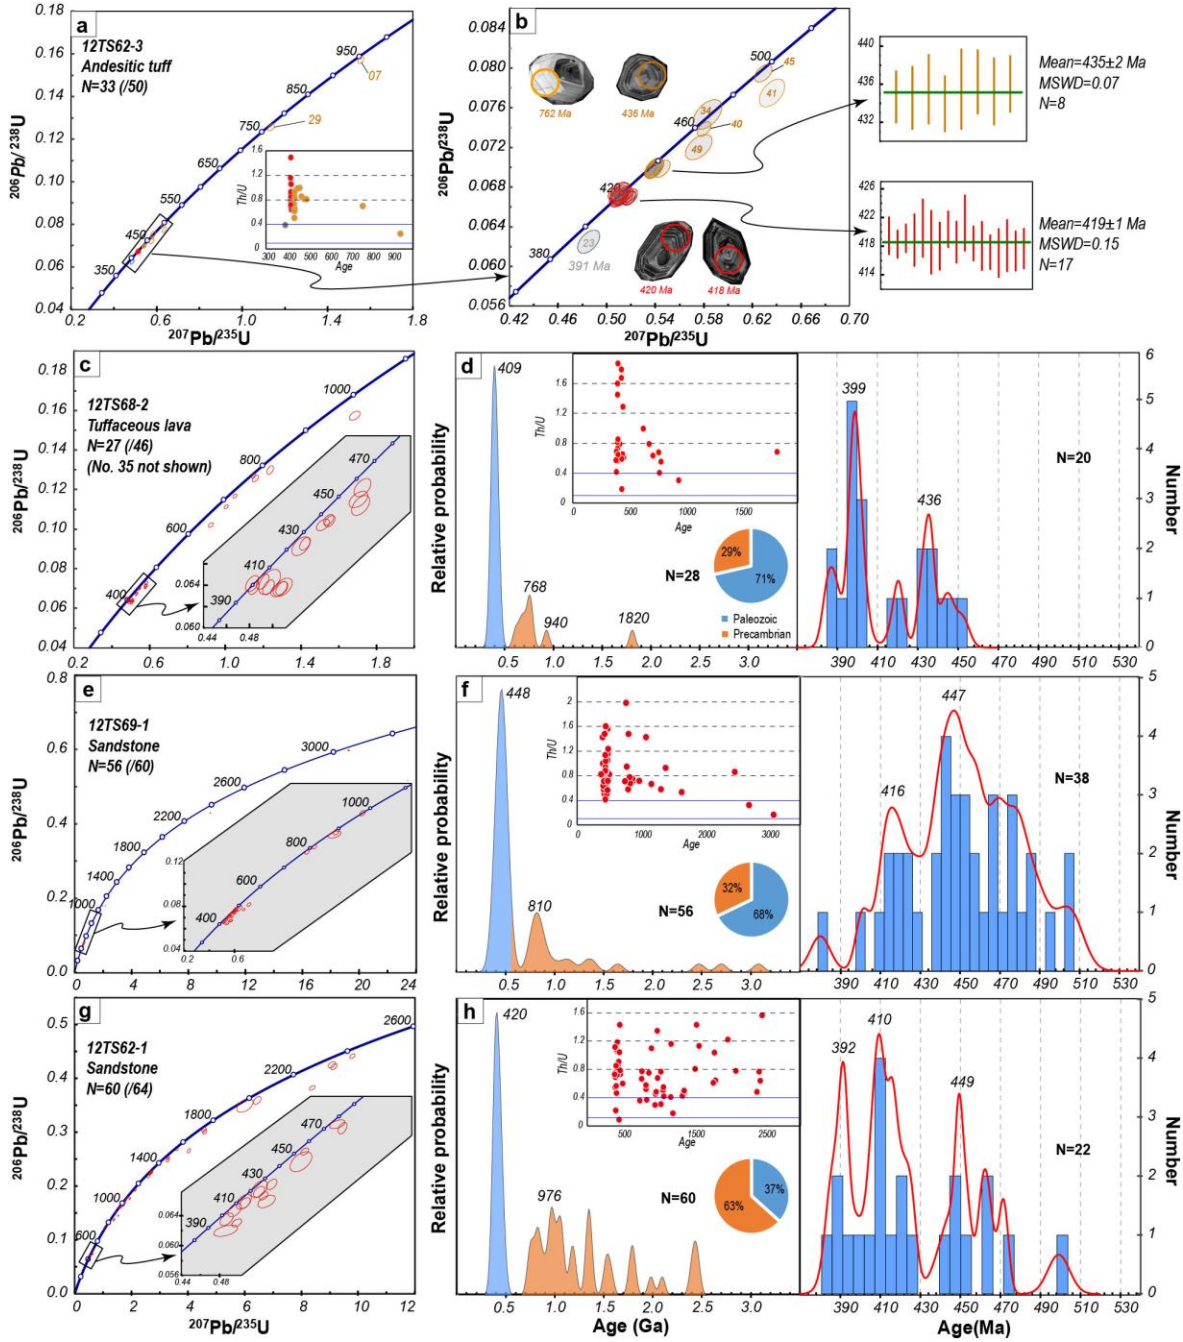

Fig. 10 Zircon U-Pb Concordia diagrams (a-c, e and g), relative density curves and histograms (d, f and h), and Th/U ratios vs. U-Pb age plots (insets of d, f and h) for volcanoclastic rocks of the Chahan-Wusu section. The CL images of all dated zircons are shown in supplementary Fig. S5.

4.3 Whole-rock Geochemical Compositions

The analytical methods for whole-rock major and trace element determination are presented in the supporting information. The bulk geochemical compositions of the Silurian-Early Devonian deformed magmatic rocks (ca. 433-419 Ma) and late Carboniferous undeformed granites and migmatites (ca. 304 Ma) are listed in supplementary [Table S3](#).

The Silurian-Early Devonian andesitic tuffs from Chahan-Wusu section and granodiorites in the Kerguty section have a moderate loss on ignition (LOI) of 1.96-3.42 wt.%, which implies slight alteration or weathering ([Table S3](#)). These magmatic rocks belong to intermediate to felsic rocks ($\text{SiO}_2=53.08\text{-}68.75$ wt.%) and have Al_2O_3 contents of 12.81-18.31 wt.% ([Table S3](#)). In the Zr/TiO₂ vs. Nb/Y classification diagram, they plot in the andesite/granodiorite field ([Fig. 11a](#)). They show relatively high TiO₂ (0.51-0.95 wt.%), FeO^T (3.50-9.14 wt.%) and total alkalis (Na₂O + K₂O; 6.15-8.25 wt.%), and variable MgO contents (2.32-7.15 wt.%) and moderate Mg[#] values (51-60) ([Table S3](#)). In the A/NK vs. A/CNK and Na₂O+K₂O - FeO^T - MgO diagrams, these samples plot in the metaluminous and calc-alkaline series domains ([Fig. 11b](#) and [c](#)). Their total rare earth element (REE) contents range from 76.2 to 289.6 ppm ([Table S3](#)), and the Chondrite-normalized REE patterns ([Fig. 12a](#)) are characterized by slightly negative Eu anomalies ($\delta\text{Eu}=0.8\text{-}1.0$) ([Fig. 12a](#) and [Table S3](#)), enrichment of light rare earth elements (LREEs; $(\text{La}/\text{Yb})_{\text{CN}}=4.9\text{-}21.3$, $(\text{La}/\text{Sm})_{\text{CN}}=3.8\text{-}7.2$) with flat heavy rare earth element patterns (HREE; $(\text{Gd}/\text{Lu})_{\text{CN}}=1.2\text{-}2.4$) ([Table S3](#)). In the mid-ocean-ridge basalt (MORB)-normalized trace element diagram ([Fig. 12b](#)), these magmatic rocks are relatively enriched in large ion lithophile elements (LILE; K, Rb, Ba and Th), and depleted in Nb, Ta, P and Ti.

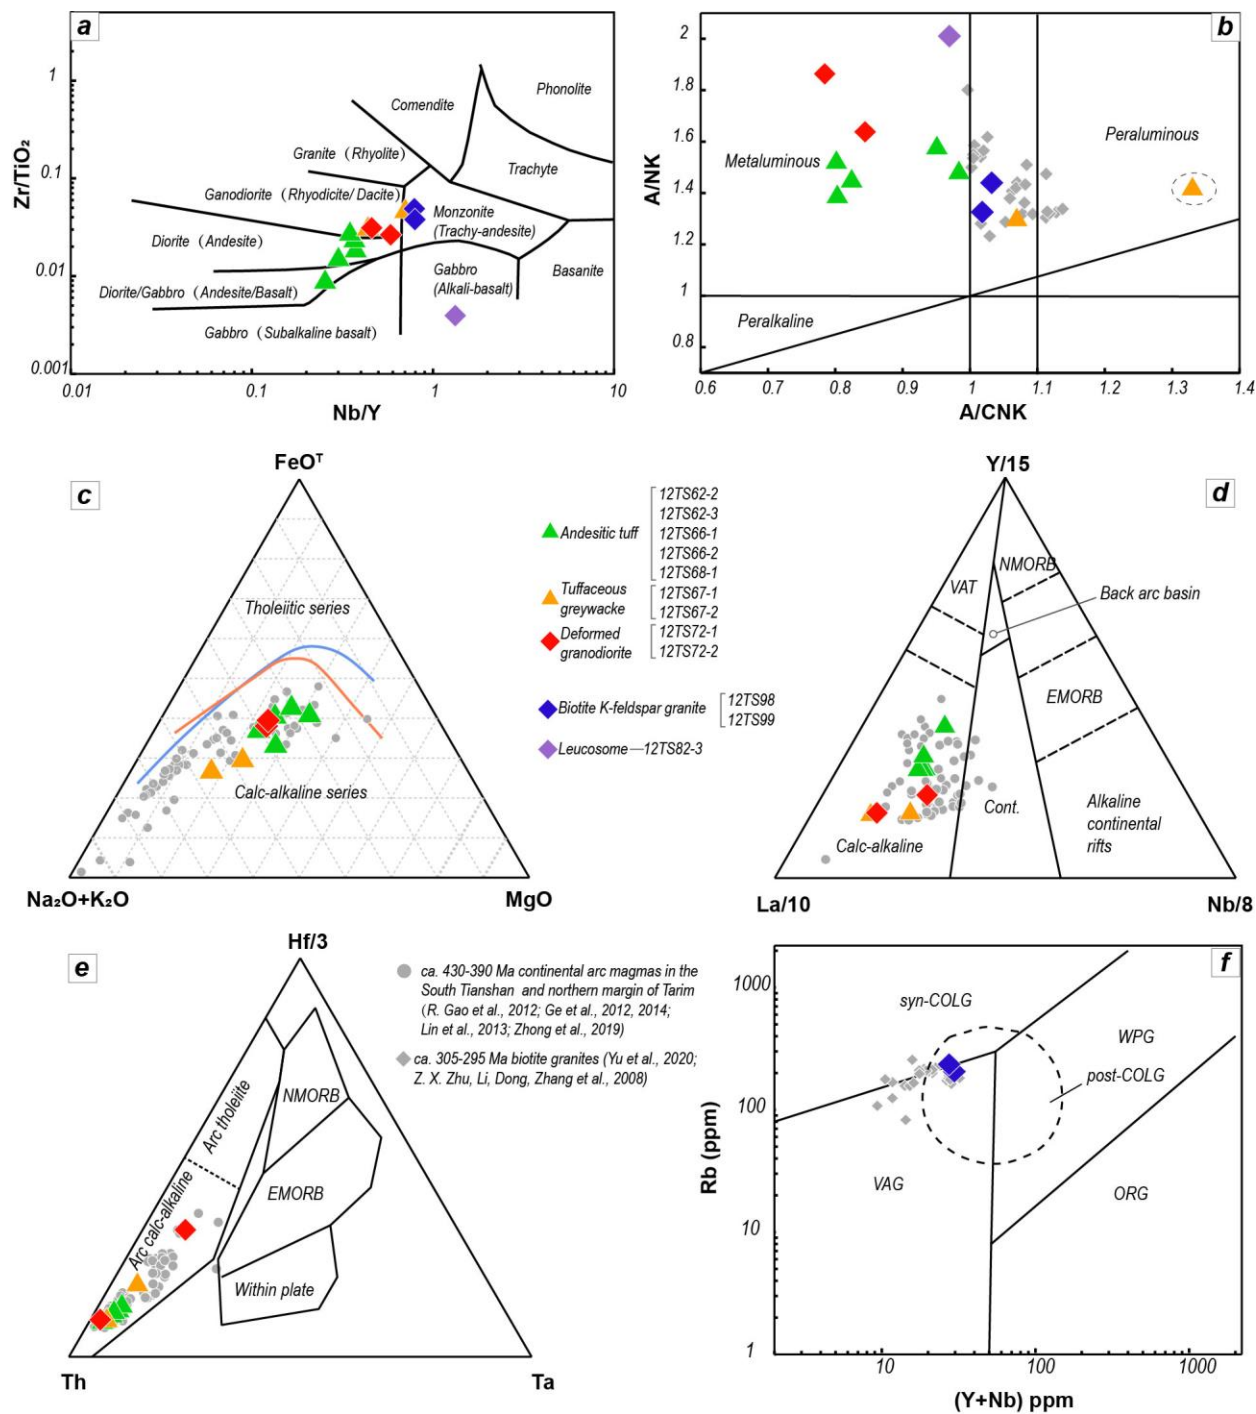

Fig. 11 Classification and tectonic determination diagrams for the magmatic rocks. (a) Zr/TiO₂ vs. Nb/Y diagram (after Winchester & Floyd, 1977). (b) A/NK vs. A/CNK diagram. (c) ALK-FeO^T-MgO diagram (after Irvine & Baragar, 1971; Kuno, 1968). (d) La/10-Y/15-Nb/8 diagram (after Cabanis & Lecolle, 1989). (e) Th-Hf/3-Ta diagram (after Wood, 1980). (f) Rb vs. Y+Nb diagram (after Pearce et al., 1984).

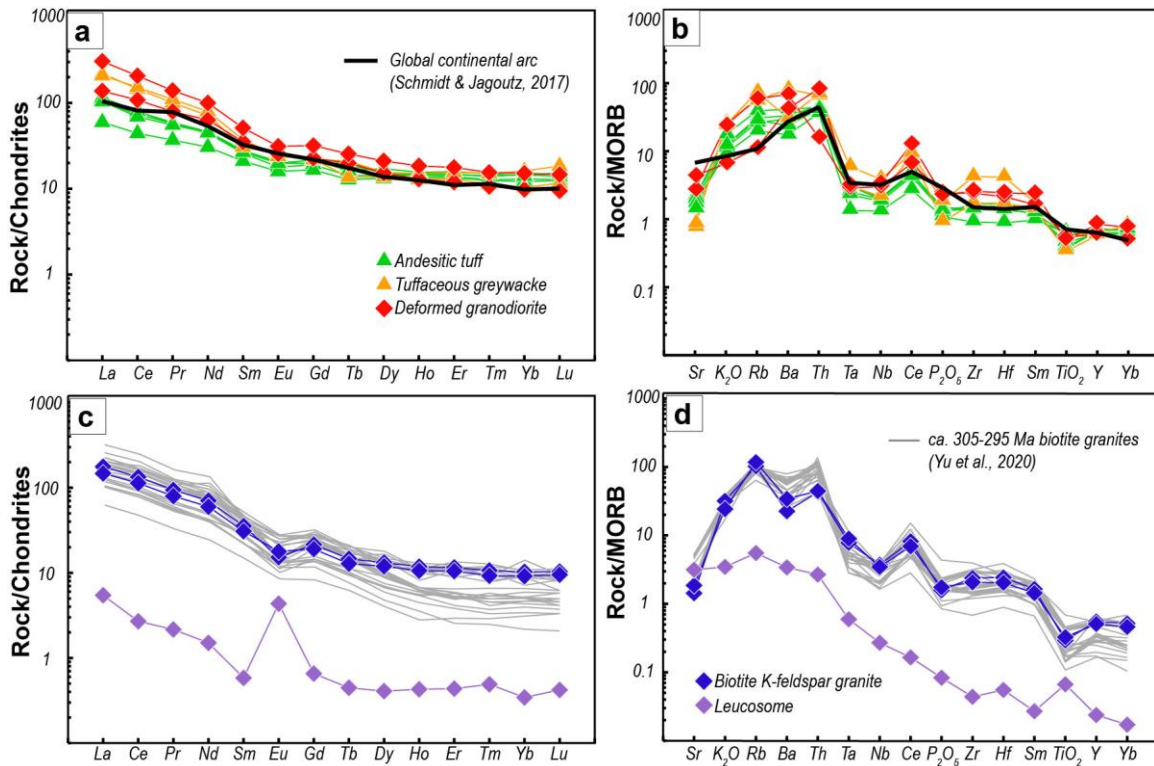

Fig. 12 Chondrite-normalized REE diagrams (a, c) and MORB-normalized trace elemental spider diagrams (b, d) of the Silurian-Early Devonian deformed magmatic rocks and Late Carboniferous undeformed granites and leucosome from the Chahan-Wusu and Kerguty sections. The normalization values for Chondrites are from Sun and McDonough (1989). The normalization values for MORB are from Pearce (1983). Abbreviations: REE-rare earth element; MORB-mid ocean ridge basalt.

The late Carboniferous biotite K-feldspar granites and leucosome show low LOI (0.82-1.00 wt.%) (Table S3). The undeformed biotite K-feldspar granites have moderately high SiO₂ (68.38-72.10 wt.%), Al₂O₃ (13.48-15.90 wt.%) and total alkalis (Na₂O + K₂O; 6.93-8.92 wt.%) contents, but relatively low MgO (1.04-1.24 wt.%), FeO^T (2.15-2.56 wt.%) and TiO₂ (0.44-0.49 wt.%) contents (Table S3). Their high A/NCK (1.02-1.03) and A/NK (1.33-1.44) values suggest that they are peraluminous rocks (Fig. 11b and Table S3). These granites display LREE-enriched chondrite-normalized REE patterns (Fig. 12c) with (La/Yb)_{CN}=16.0-17.0, (La/Sm)_{CN}=4.8-5.0, (Gd/Lu)_{CN}=2.0-2.1, and negative Eu anomalies (δ Eu=0.5-0.7) (Fig. 12c and Table S3). In the

1
2
3
4 521 MORB-normalized trace element diagram, these granites show enrichment of LILEs and depletion
5
6
7 522 of Ba, Ta, P and Ti (Fig. 12d).

8
9 523 The leucosome sample has relatively high Al₂O₃ (21.31 wt.%), CaO (6.25 wt.%) and Na₂O
10
11 524 (6.10 wt.%) contents, moderate SiO₂ (63.88 wt.%) abundance, and very low contents of other
12
13
14 525 oxides (Table S3). It is extremely depleted in REEs with total REE of 4.6 ppm, and shows highly
15
16 526 positive Eu anomaly ($\delta\text{Eu}=7.0$) (Fig. 12c and Table S3). The leucosome is relatively enriched in
17
18
19 527 LILEs, but highly depleted in high field strength elements (HFSEs) (Fig. 12d). All these features
20
21 528 are consistent with anatexis of a pelitic protolith.

22
23
24 529

25 26 530 **5. Discussion**

27 28 29 531 **5.1 Early-Middle Paleozoic Continental Arc and Back-arc Extension**

30 31 532 **5.1.1 Tectonic setting of magmatic rocks in the Central and South Tianshan**

32
33 533 It is well accepted that early-middle Paleozoic magmatic rocks in the Central Tianshan
34
35
36 534 (CTS) were generated in a continental arc setting, whereas the tectonic setting of the South
37
38 535 Tianshan (STS) remains contentious. Some researchers considered the STS as a wide accretionary
39
40
41 536 complex (Xiao et al., 2013), or an intra-oceanic terrane set accreted to the passive northern margin
42
43 537 of the Tarim craton (Gao et al., 1998; Han et al., 2011), while others advocated that part of the
44
45
46 538 STS represented a continental arc comparable to the CTS (Gao et al., 2012; Ge et al., 2012, 2014;
47
48 539 Lin et al., 2013; Zhong et al., 2019; Zhu, Li, Dong, Wang, et al., 2008). The focus of debate is
49
50
51 540 whether the magmatic rocks in the STS and northern Tarim formed in subduction-related settings,
52
53 541 and whether the STS overlies a continental basement.

54
55 542 Our new data indicate that the Silurian-Early Devonian metaluminous, high-potassium and
56
57
58 543 calc-alkaline intermediate volcanic rocks from the STS and granodiorites from the Baluntai area

61
62
63
64
65

of the CTS show common geochemical characteristics (Fig. 11 and 12). Their enrichment in LILE and LREE, and depletion in HFSE probably resulted from partial melting of the fluid-metasomatized mantle wedge above the subducted slab and/or contamination by the continental crust (e.g., Pearce & Peate, 1995). Our magmatic samples are highly consistent with the typical continental arc-type calc-alkaline basalts (Schmidt & Jagoutz, 2017) in terms of Chondrite-normalized REE and MORB-normalized trace element patterns (Fig. 12a and b). In the La/10-Y/15-Nb/8 and Th-Hf/3-Ta discrimination diagrams, all our samples plot in the field of calc-alkaline series in continent-based magmatic arcs (Fig. 11d and e). In agreement with several previous studies on the magmatic rocks of neighboring areas (i.e., Huolashan and Erbinshan) (Gao et al., 2012; Ge et al., 2012, 2014; Lin et al., 2013; Zhong et al., 2019; Zhu, Li, Dong, Wang, et al., 2008), it is confirmed that early Paleozoic subduction-related magmatism occurred in the STS and northern margin of Tarim, and is comparable with that in the CTS.

Our new zircon U-Pb ages suggest that the volcanic rocks in the Chahan-Wusu section erupted at ~420 Ma. The occurrence of inherited early Neoproterozoic and early Paleozoic magmatic zircons (Fig. 10a and b) indicates that the Neoproterozoic-early Paleozoic crustal rocks were involved in magma generation or assimilated during magma ascension. In addition, Archean to Mesoproterozoic xenocrystic zircons also commonly occur in the early Paleozoic arc-type magmatic rocks from the STS (e.g., Alexeiev et al., 2015; Zhong et al., 2019). According to the available age and Lu-Hf isotopic data, the early-middle Paleozoic arc-type magmatic rocks (470-390 Ma) in the STS are characterized by negative to slightly positive $\epsilon_{\text{Hf}}(t)$ values and Neo- to Paleoproterozoic (0.7-2.0 Ga) two-stage Hf model ages (Fig. 13 and Table S4, S5). These data suggest significant contributions of the persistently recycled continental crust to the magma sources of the arc magmatism. Interestingly, the zircon $\epsilon_{\text{Hf}}(t)$ values of many single samples of

1
2
3
4 567 early-middle Paleozoic magmatic rocks in the STS are highly variable (Zhong et al., 2019), such
5
6 568 obvious Hf isotopic heterogeneity and evolution trend could be probably attributed to magma
7
8 569 mixing (and/or assimilation) instead of magma differentiation (Griffin et al., 2002; Kemp et al.,
9
10
11 570 2005, 2007), and the ancient continental crust was likely the predominant end member for the
12
13
14 571 magma mixing, and the depleted mantle wedge contributed juvenile components.

48
49 572
50 573 **Fig. 13** (a) Sketch illustration and relative density curves of compiled radiometric ages of 500-250 Ma
51
52 574 magmatic rocks and ophiolites in southern Yili block (SYB), Central Tianshan (CTS), South Tianshan
53
54 575 (STS) and northern margin of the Tarim craton (NTC; see data sources in Table S4). (b-e) Compiled zircon
55
56 576 Hf isotopic compositions from Paleozoic magmatic rocks in SYB, CTS, STS and NTC (see data sources in
57
58 577 Table S5).
59
60
61
62
63
64
65

1
2
3
4 579 Thus, the early-middle Paleozoic magmatism in the STS formed in an active continental
5
6 580 margin, coeval to the magmatic arc activity in the CTS. In addition, moderate $(La/Yb)_{CN}$ (4.9-
7
8 581 21.3), Sr/Y (5.2-13.3), and slightly negative Eu anomalies (0.8-1.0) (Table S3) of the arc-type
9
10 582 magmatic rocks suggest that plagioclase was negligible in the residue, indicating partial melting
11
12 583 of a normal to slightly thickened continental crust (20-45 km). The thickening of the arc crust
13
14 584 might have resulted from advancing subduction of the Paleo-Tianshan Ocean during the early
15
16 585 Paleozoic (Liu et al., 2022; X. S. Wang et al., 2020).
17
18
19
20

21 586 5.1.2 Deposition ages, provenances, and paleo-geographic environment of the (meta-) 22 23 587 sedimentary rocks 24 25

26 588 The (meta-) sedimentary rocks from the Kerguty and Chahan-Wusu sections were both
27
28 589 ascribed to the Devonian Sa'erming Group by XBGMR (1993), in spite of poorly constrained age.
29
30 590 These (meta-) sedimentary rocks show unimodal distribution of detrital zircon ages (Fig. 9 and
31
32 591 10), according to Dickinson and Gehrels (2009), the major and/or the youngest peak age of the
33
34 592 zircon populations can be used to constrain the (maximum) depositional ages of the (meta-)
35
36 593 sediments, while youngest single zircon ages if any, could represent post-depositional
37
38 594 metamorphic overprints.
39
40
41
42

43 595 In the meta-sandstone sample 12TS73-1 from the Kerguty section, the detrital zircons show
44
45 596 a unimodal age of ~435 Ma, but they contain a youngest zircon population (~412 Ma) (Fig. 3, 9a
46
47 597 and 9b) showing homogeneously black CL images and low Th/U ratios (<0.1) (Fig. S4), these
48
49 598 youngest zircons were most likely affected or produced by post-depositional metamorphism or
50
51 599 hydrothermal fluid activity; the second Paleozoic zircon population has a peak at ~446 Ma (Fig.
52
53 600 9b) and is mainly composed of detrital zircons of magmatic origin (Fig. S4). Thus, the meta-
54
55 601 sandstone was likely deposited during the ~435-412 Ma interval. The paragneiss samples 12TS82-
56
57
58
59
60
61
62
63
64
65

1
2
3
4 602 1 and 12TS93-1 show unimodal ages of ~421 Ma and ~444 Ma, and their youngest detrital zircon
5
6 603 age peaks are ~425 Ma and ~420 Ma, respectively (Fig. 9d and f), the maximum depositional age
7
8
9 604 of their protolith is therefore constrained at 421-420 Ma.

10
11 605 Similarly, the tuffaceous clastic samples 12TS68-2, 12TS69-1 and 12TS62-1 from the
12
13
14 606 Chahan-Wusu section, display unimodal ages at ~409 Ma, ~448 Ma and ~420 Ma, but in detailed
15
16 607 spectra of Paleozoic ages, their youngest age peaks are ~399 Ma, ~416 Ma and ~392 Ma,
17
18
19 608 respectively (Fig. 10d, f and h). Considering that most detrital zircons in these (meta-) sedimentary
20
21 609 rocks are euhedral-subhedral (Fig. S5), their depositional ages are therefore constrained at 416-
22
23
24 610 392 Ma.

25
26 611 Excluding the zircon grains disturbed by post-depositional metamorphism and those with
27
28
29 612 unclear or meaningless ages (e.g., samples 12TS73-1 and 12TS69-1), the (meta-) sedimentary
30
31 613 rocks contains 64% of Paleozoic (178 out of total 280) and 36% of Precambrian (102 out of 280)
32
33 614 detrital zircons (Fig. 14 and Table S2). The Paleozoic zircons (ca. 500-380 Ma) show angular or
34
35
36 615 sub-angular shapes and form a unimodal age peak for each sample, they were most likely derived
37
38
39 616 from nearby and identical magmatic provenances. As discussed above, early-middle Paleozoic arc
40
41 617 magmatic rocks are well developed both in the CTS and STS, and previous studies also
42
43 618 documented Paleozoic continental arc rocks on the northern margin of the Tarim craton (e.g., Ge
44
45
46 619 et al., 2012, 2014; Huang et al., 2013; Lin et al., 2013; Zhao et al., 2015); thus, the arc-type
47
48 620 magmatic rocks in the CTS, STS and northern Tarim are possible sources for the Paleozoic detrital
49
50
51 621 component of the studied Silurian-Devonian (meta-) sedimentary rocks of the STS. The north-
52
53 622 directed (present coordinates) paleocurrent documented by the sedimentary structures of the
54
55
56 623 tuffaceous clastic rocks of the Chahan-Wusu section (Fig. 2, 6a and 6e-g), favors a southern
57
58 624 provenance, i.e., from the northern Tarim. For the same reason, the Precambrian detritus in the

65

625 studied (meta-) sedimentary rocks may also have derived from Tarim. It is noteworthy that the
626 paleocurrent direction of meta-sedimentary rocks in the Kerguty section could not be determined
627 due to intense metamorphism and deformation. However, the comparison of Precambrian zircon
628 age spectra between the late Silurian-Devonian sedimentary rocks in the STS-CTS and the coeval
629 sedimentary rocks of northern Tarim suggests that the Tarim craton was the source region for the
630 early Paleozoic sediments of CTS and STS (Fig. 14) (Ma, Shu, Santosh, et al., 2012; B. Wang et
631 al., 2018).

632 In the cumulative proportion vs. crystallization age-deposition age diagram (Fig. 15)
633 (Cawood et al., 2012), the curves generated by our (meta-) sedimentary rocks mostly show that
634 the ages of more than 50% of detrital zircons are close to the depositional ages, indicating a
635 sedimentary basin close to the active magmatic arc and thus formed in the supra-subduction zone
636 (convergent margin in Cawood et al., 2012). There is a neat southward increase of the proportion
637 of Precambrian zircons sourced in the Tarim along the Chahan Wusu section (samples 12TS68-2
638 (29%), 12TS69-1 (32%) and 12TS62-1 (63%)) (Fig. 10 and 15). As these rocks accumulated in a
639 sedimentary basin located between the CTS arc and the active margin of northern Tarim, such
640 southward increase is consistent with sedimentary records in a back-arc basin (Cawood et al., 2012)
641 that was located on the southern flank of the Central-South Tianshan continental arc. The same
642 feature appears in the samples of the Kerguty section (Fig. 9 and 15).

643

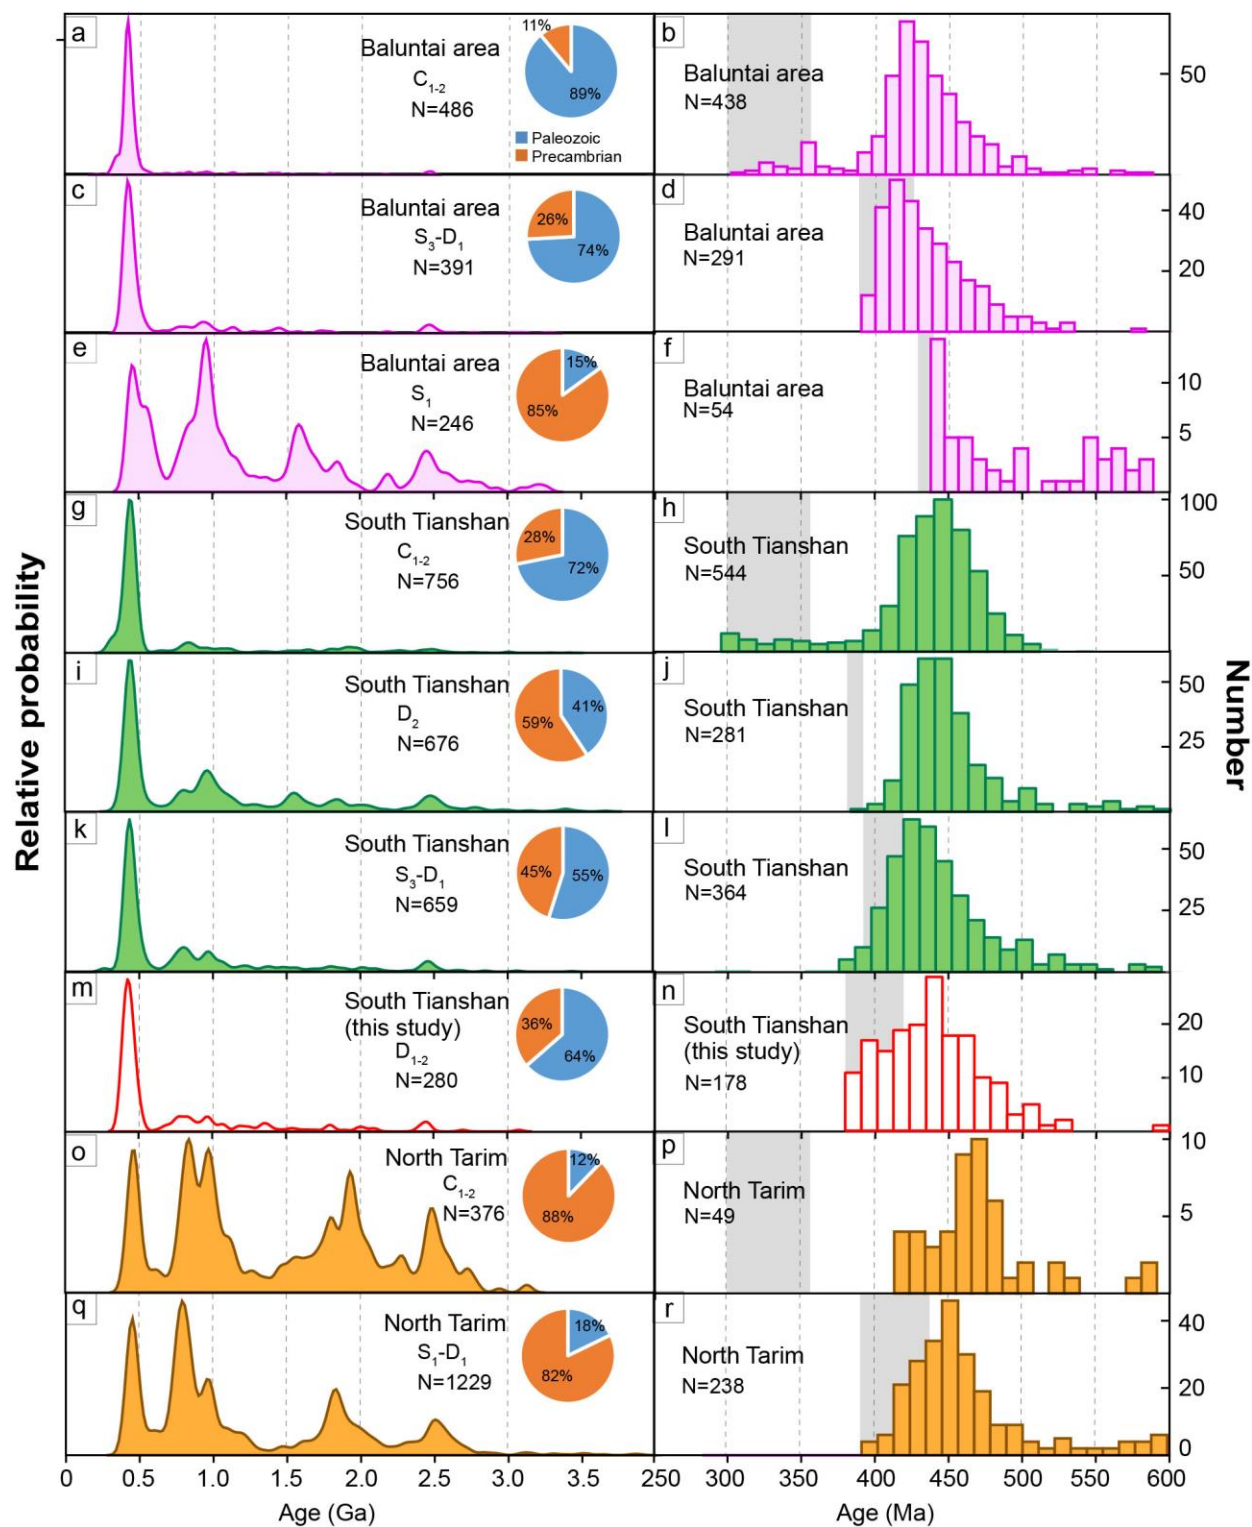

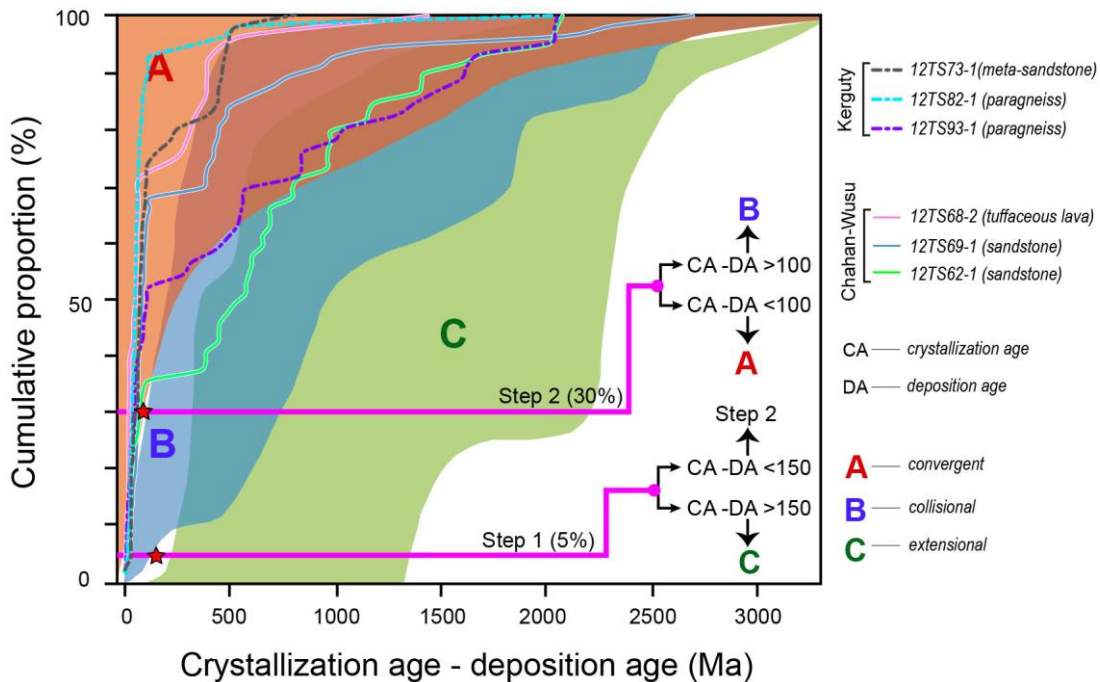

Fig. 14 Relative density curves (4.0-0 Ga) and histograms (600-250 Ma) for compiled detrital zircon U-Pb ages of (meta-)sedimentary rocks with different depositional ages (indicated by grey bars) from the Baluntai area of the Central Tianshan, South Tianshan and North Tarim (see data sources in [Table S6](#)).

1
 2
 3
 4 649 Sedimentary sequences of Upper Silurian calcareous flysch and Lower Devonian
 5
 6 650 limestones, cherty limestones and cherts (from bottom to top) in the STS record a deepening of
 7
 8
 9 651 the depositional environment from neritic to abyssal facies during the middle Paleozoic (Charvet
 10
 11
 12 652 et al., 2007, 2011; B. Wang et al., 2008). Besides, such a back-arc spreading setting is in agreement
 13
 14 653 with the occurrence of Silurian to Early Devonian SSZ-type ophiolitic mélanges in the STS, i.e.,
 15
 16 654 the Kulehu-Serikeyayilake-Aertengkesi-Mandaleke, Yushugou-Tonghuashan, and Wuwamen-
 17
 18
 19 655 Guluogou ophiolite belts (Gao et al., 1998; Han et al., 2011; Jiang et al., 2014; Long et al., 2006;
 20
 21 656 Ma et al., 2007; B. Wang et al., 2011b, 2018; Yang et al., 2011), indicating the development of a
 22
 23
 24 657 series of back-arc basins in the STS (B. Wang et al., 2018; Zhong et al., 2019). Therefore, a
 25
 26 658 continental arc-back-arc extension is suggested to have existed during the early-middle Paleozoic
 27
 28
 29 659 in the Central and South Tianshan.

 57 663

5.2 Post-collisional Extension with Crustal Anatexis in the South Tianshan

It is generally accepted that migmatite is formed by partial melting (i.e., anatexis) of continental crust rocks and migmatization is known to be a mode forming leucogranites (Yakymchuk, 2021). Based on our field observations in the migmatitic unit of the Kerguty section, the rootless lensoid or pygmatic structure of leucosome, material exchange and inter-diffusion between the leucogranite and surrounding paragneiss and amphibolite, both transitional and sharp contact between the leucosome and mesosome or melanosome occur simultaneously, suggesting the co-existence of in-situ partial melting, aggregation and migration of melts (Berger & Kalt, 1999; Sawyer, 1996, 1999). On the Kerguty section, there is a progressive evolution from the Devonian metasediments (schist, paragneiss, limestone) into the migmatites (Fig. 3b). Furthermore, according to the biotite-enriched melanosome and mineral assemblage of muscovite + plagioclase + quartz in the leucosome (Fig. 3 and 4), it is therefore likely that parts of protolith of the migmatites in the STS are the Devonian meta-sedimentary rocks (meta-sandstones/pelites). Geochemical features of the leucosome sample (12TS82-3) is characterized by significantly high Al_2O_3 , Na_2O , CaO and Sr contents, as well as extremely low REE concentrations and positive Eu anomaly (Fig. 12c and Table S3), indicating a plagioclase-rich cumulate melt rather than the initial anatectic melt (Sawyer, 2008).

Our zircon U-Pb dating on three migmatites and associated meta-sedimentary rocks yielded complex results. The diatexite sample 12TS80-2 contains a dominant age population of 450 ± 3 Ma and three ages around ~ 420 Ma (No. 7, 10 and 11), which are consistent with main age populations of the paragneiss (metatexite) samples 12TS82-1 and 12TS93-1 (Fig. 8b, 9 and S2). Considering the rock assemblages and field geometric relationships (Fig. 3 and 4), the diatexite and surrounding metatexite or paragneiss could represent the products of higher and lower degrees of partial melting

1
2
3
4 687 of similar protoliths, respectively. Thus, the aforementioned ages of ~450 Ma and ~420 Ma of
5
6 688 sample 12TS80-1 most likely represent the detrital zircon ages in their protoliths. Another two
7
8
9 689 ages of ~420 Ma on the overgrown rims (No. 2 and 6) are most likely be the mixing age of the
10
11 690 inherited cores and metamorphic rims, similar to the zircon ages (~412 Ma) in sample 12TS73-1
12
13
14 691 (Fig. 8b, 9b and S3). The leucogranite sample 12TS95 yielded a dominant age at 304 ± 3 Ma (Fig.
15
16 692 8a). The corresponding zircons have regular shapes, no or weakly zoned internal texture with low
17
18
19 693 CL intensity, and their Th/U ratios are mostly lower than 0.1 (Fig. S3), similar to the metamorphic
20
21 694 zircons in amphibolite-facies rocks (Wu & Zheng, 2004). The age of 332 ± 3 Ma on the bright cores
22
23
24 695 of six zircons from the leucosome (12TS82-3) appears to reveal an early high-grade metamorphism
25
26 696 overprinted by the later migmatization (Fig. 8c, 8d and S3). Alternatively, it could be due to a
27
28
29 697 protracted crust melting from 332 to 304 Ma in an evolving tectonic setting (e.g., syn to late or
30
31 698 post-collision). Anyway, the latest Carboniferous (~304 Ma) anatectic event in the STS can be
32
33
34 699 confirmed at least.

35
36 700 In general, it is difficult to reach the P-T conditions for partial melting of the supracrustal
37
38 701 rocks to generate felsic magma under the normal geothermal gradient. In the study area, previous
39
40
41 702 studies on the latest Carboniferous (ca. 305-295 Ma) magmatic rocks indicate a negligible
42
43 703 involvement of mantle components (Yu et al., 2020; Zhu, Li, Dong, Zhang et al., 2008). Instead,
44
45
46 704 high Sr/Y and $(La/Yb)_{CN}$ of the ~300 Ma granitoids in the STS suggest the existence of thickened
47
48 705 crust (Han et al., 2019; Yu et al., 2020; Zhu, Li, Dong, Zhang et al., 2008 and this study). Although
49
50
51 706 nature of the garnet from the studied leucogranite is unknown, contemporaneous garnet-bearing
52
53 707 granites/rhyolites (ca. 310-300 Ma) exposed in the STS-Tarim border region indicate a high
54
55
56 708 pressure source region ($P > 7$ kbar) (Cheng et al., 2017; Qin et al., 2021). In fact, significant crustal
57
58 709 thickening commonly occurs at convergent margins where supracrustal sedimentary rocks can be
59

64
65

710 buried into middle-lower crustal depth, and decompressional partial melting during late or post-
711 orogenic collapse of orogens resulted in the anatexis of the middle-lower crust, favoring the
712 generation of leucogranites, as observed in the collisional Himalaya Orogen (e.g., [Brown, 1994](#);
713 [Harris & Massey, 1994](#); [Nabelek & Liu, 2004](#)). Considering the latest Carboniferous high-
714 potassium and peraluminous granites with post-collisional features in the study area ([Fig. 11b](#) and
715 [f](#)) ([Yu et al., 2020](#); [Zhu, Li, Dong, Zhang et al., 2008](#)), we speculate that the latest Carboniferous
716 magmatism and migmatization may both result from crustal melting in response to a collisional
717 orogeny in the STS.

718 Although controversies remain, most researchers agree that the Paleozoic South Tianshan
719 was formed by the collision of the Kazakhstan microcontinent (here represented by the Yili and
720 Central Tianshan blocks) with the Tarim craton (e.g., [Alexeiev et al., 2015](#); [Charvet et al., 2011](#);
721 [Gao et al., 1998, 2009](#); [Han et al., 2010, 2011](#); [Han & Zhao, 2018](#); [Liu et al., 2022](#); [Xiao et al.,](#)
722 [2008, 2013](#); [B. Wang et al., 2011b, 2018](#); [X. S. Wang et al., 2022](#); [Zhong et al., 2019](#)). According
723 to the ages of undeformed granite dykes crosscutting the Wuwamen ophiolitic mélangé and
724 HP/UHP metamorphic belts in the STS, the final amalgamation of these blocks would not be later
725 than 300 Ma ([Gao et al., 2009](#); [B. Wang, Shu, et al., 2007, 2018](#); [X. S. Wang et al., 2022](#)). Besides,
726 from Carboniferous to Permian, the continuous evolution of magmatism from calc-alkaline to
727 alkaline series in the Yili-Central Tianshan domain, displays the typical characteristics of post-
728 collisional magmatism ([Seltmann et al., 2011](#); [B. Wang et al., 2009](#)), while coeval post-collisional
729 magmatic rocks are widespread in the STS and northern Tarim ([Konopelko et al., 2007](#); [Ma et al.,](#)
730 [2015](#)). In addition, our new structural analyses on the Central and South Tianshan support the
731 transition from the collisional compression to post-collisional extension during the late
732 Carboniferous (see section 5.3). Therefore, the latest Carboniferous migmatization and

peraluminous magmatism reasonably reflect the onset of post-collisional extension, which is consistent with the rising temperature of the magma source from 300 to 280Ma (Cheng et al., 2017). Meanwhile, the buoyant ascending of the anatexitic crustal materials could further accelerate the regional extension and orogenic gravitational collapse (Rey et al., 2001; Vanderhaeghe, 2009).

5.3 Multi-stage Deformation and Tectonic setting

Based on our new field observations combined with the available structural data in the Central and South Tianshan, we summarize and discuss the geodynamic significance of multiphase ductile to brittle-ductile deformation structures and their tectonic implications (Fig. 16 and Table 1, S7).

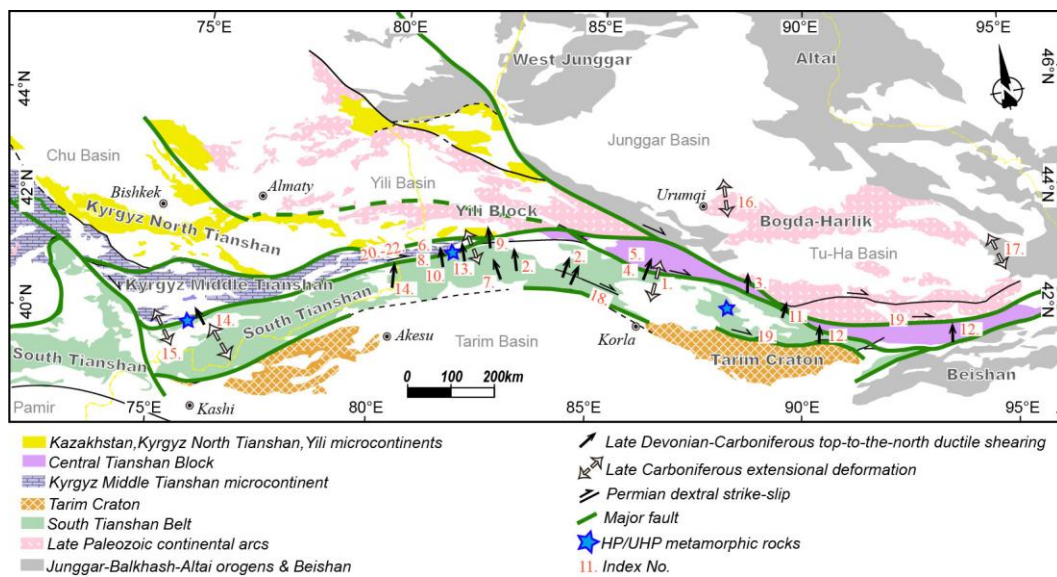

Fig. 16 Tectonic sketch map of the southern CAOB (modified after Alexeiev et al., 2015), and distribution of ductile deformation kinematics in the Central and South Tianshan (see supplementary Table S7 for data sources).

5.3.1 Late Devonian-Carboniferous compressional deformation

Our new structural observations and dating results on the deformed meta-sedimentary rocks and undeformed granites (Fig. 3b and 6a) indicate that the D_{K1-1} , D_{K1-2} , D_{K3-1} and D_{Ch-1}

1
2
3
4 750 deformation structures were generated during the Devonian-late Carboniferous. The south-verging
5
6
7 751 brittle-ductile thrust faults and folds in the STS (D_{KI-2} and D_{Ch-1}) and north-verging reverse faults
8
9 752 in the CTS (Fig. 3b, 6a and Table 1) (Li et al., 2020; Zhong et al., 2015) show an overall positive
10
11
12 753 flower structural pattern. Such thrusting of the Paleozoic (meta-) sedimentary rocks and folding of
13
14 754 the earlier foliation/original bedding in the STS (D_{KI-2} and D_{Ch-1}) likely represent the deformation
15
16 755 structures related to the CTS-Tarim collision after the final closure of the STS back-arc basin
17
18
19 756 during the latest Carboniferous (ca. 310-304 Ma) (B. Wang et al., 2018 and this study). Notably,
20
21 757 the brittle reverse faults (D_{K2-3}) crosscutting the migmatites and post-orogenic structures might
22
23
24 758 also be formed during the Cenozoic deformation induced by the India-Asia collision (Jolivet et al.,
25
26 759 2010). It should be emphasized that the widespread south-verging fold-and-thrust in the STS could
27
28
29 760 be related to Paleozoic orogenic deformation and partly to Cenozoic reactivation (Loury et al.,
30
31 761 2015; B. Wang et al., 2011b; Zhong et al., 2019), such as the reactivation structure D_{Ch-3} (brittle
32
33 762 south-verging thrusting) of the D_{Ch-1} (brittle-ductile deformation) in the Chahan-Wusu section
34
35
36 763 (Fig. 6a and Table 1).

37
38 764 According to previous data and our new results, the top-to-the-north ductile shear
39
40
41 765 kinematics (D_{KI-1} and D_{K3-1}) (Fig. 3b and Table 1) correspond to the oldest and most extensively
42
43 766 preserved structures in the Central and South Tianshan units (Fig. 16 and Table S7). In the adjacent
44
45 767 Wuwamen-Guluogou ophiolitic mélanges and Baluntai area, macro to microscale asymmetric
46
47
48 768 fabrics with top-to-the-north shearing kinematics are well developed in the ductilely deformed
49
50
51 769 Paleozoic rocks (Fig. 16) (B. Wang et al., 2018; Zhong et al., 2015), which are consistent with the
52
53 770 D_{KI-1} and D_{K3-1} structures in the Kerguty section (Fig. 3b). In addition, in contrast to the ductile
54
55
56 771 deformation of the gneiss in the CTS, the brittle-ductile structures of lower greenschist facies
57
58 772 metasediments in the STS are geometrically consistent with that of the hanging wall of a south-

1
2
3
4 773 dipping subduction zone (Fig. 2, 3b and 6a). Therefore, the earliest top-to-the-north shearing
5
6 774 throughout the Kerguty section might be linked with the southward subduction of the Wuwamen-
7
8
9 775 Guluogou back-arc basin during the late Carboniferous (B. Wang et al., 2018). Besides, similar
10
11 776 north-verging thrusting has also been widely recognized in the southern ophiolite belt and
12
13
14 777 Kuikewusu-Kaidu magmatic arc of the STS (Fig. 16) (Alexeiev et al., 2015; B. Wang et al., 2011b;
15
16 778 Zhong et al., 2019), corresponding to the Late Devonian-early Carboniferous southward
17
18
19 779 subduction of other back-arc basins in the South Tianshan (until ca. 359-356 Ma) (B. Wang et al.,
20
21 780 2011b; Zhong et al., 2019).

23 781 5.3.2 Latest Carboniferous extension and gneiss doming

24
25
26 782 The latest Carboniferous tectono-metamorphic events (D_{K2-1}) (Fig. 3b, 16 and Table 1) in
27
28
29 783 the STS suggest the occurrence of a migmatite-cored gneissic dome resulting in the exhumation
30
31 784 of the anatectic middle crust and reflecting the gravitational collapse of the orogen. In the orogenic
32
33
34 785 cycle, gravitational collapse can occur during syn- and post-orogenic processes, and result in
35
36 786 transition from crustal thickening to crustal thinning (Jamieson et al., 2011; Rey et al., 2001;
37
38 787 Vanderhaeghe, 2009; Vanderhaeghe & Teyssier, 2001). During syn-orogenic collapse, the melt-
39
40
41 788 weakened middle crust is transported laterally by extrusion and thrusting; this was characterized
42
43 789 in the Himalaya-Tibet Orogen (Beaumont et al., 2001; Block & Royden, 1990; Grujic et al., 1996;
44
45 790 Jamieson et al., 2011). Accordingly, the proposed channel flow is bounded by ductile thrust faults
46
47
48 791 at the bottom and ductile normal faults at the top (Beaumont et al., 2001; Block & Royden, 1990;
49
50 792 Grujic et al., 1996; Jamieson et al., 2011; Vanderhaeghe & Teyssier, 2001). However, this model
51
52
53 793 is obviously inconsistent with the field and microscopic structural features of the extensional
54
55 794 doming recognized in the STS (D_{K2-1}) (Fig. 3b and 16). By contrast, the post-orogenic collapse is
56
57
58 795 usually characterized by detachment at the upper crust level and extensional ductile deformation
59
60
61
62
63
64
65

1
2
3
4 796 at the middle crust (He et al., 2016; Rey et al., 2001). The D_{K2-1} deformation observed in the
5
6
7 797 Kerguty section likely formed during the post-orogenic collapse, although no upper normal fault
8
9 798 is preserved probably due to extensive denudation (Rey et al., 2001). Nevertheless, it is difficult
10
11
12 799 for an exhumed ancient orogen to determine whether crustal melting was the consequence or the
13
14 800 trigger of extensional collapse, because of positive feedbacks between the two processes (England
15
16 801 & Molnar, 1993; Hodges, 1998).

18
19 802 In addition, the south-directed ductile shearing documented in the Akyazi and Atbashi
20
21 803 HP/UHP metamorphic belts (Fig. 16) overprinted the earlier top-to-the-north ductile thrusting.
22
23
24 804 This was either interpreted as ductile normal faulting induced by post-collisional extension and
25
26 805 exhumation of the HP/UHP metamorphic rocks (e.g., Louri et al., 2015; B. Wang et al., 2010), or
27
28
29 806 back-thrusting induced by the Yili-CTS collision (Lin et al., 2009). Muscovite ⁴⁰Ar/³⁹Ar ages of
30
31 807 335-310 Ma constrain the timing of exhumation of the Akyazi HP/UHP metamorphic rocks
32
33
34 808 (Klemd et al., 2005; B. Wang et al., 2010), and the unconformably overlying conglomerates
35
36 809 provided a minimum exhumation age of the Atbashi HP units at 303-295 Ma (Baslakunov et al.,
37
38 810 2007).

39
40
41 811 Late Carboniferous orogen-perpendicular extensional structures also have been recorded
42
43 812 in the Bogda-Harlik areas (Fig. 16) (Ni et al., 2021; Shu, Wang, et al., 2011; Song et al., 2022) and
44
45
46 813 southern Yili block (Liu et al., 2022). In addition, co-occurrence of widespread ~300 Ma N-S-
47
48 814 striking felsic/mafic dykes (e.g., Liu et al., 2022; Yang et al., 2011) and top-to-the-ESE (orogen-
49
50
51 815 parallel) shearing (Li et al., 2020) in the YB-CTS units argue for contemporaneous extensional
52
53 816 deformation and magmatism. These latest Carboniferous orogen-perpendicular/parallel
54
55
56 817 extensional structures, exhumation of high-grade metamorphic rocks, bimodal magmatism, and
57
58 818 early Permian crustal thinning (ca. 290-280 Ma) (Han et al., 2019) of the CTS and STS altogether
59
60
61
62
63
64
65

1
2
3
4 819 recorded the post-collisional extension and gravitational collapse in the Tianshan Orogen. Thus,
5
6
7 820 the South Tianshan collisional orogeny was terminated in the latest Carboniferous.

9 821 5.3.3 Permian transcurrent tectonics

10
11 822 Dextral strike-slip shearing was mainly localized at the E-W trending margins of the major
12
13
14 823 tectonic units in the Tianshan Orogen; i.e., along the Akyazi-Nalati Fault (Lin et al., 2009; Yin et
15
16 824 al., 1998; Yin & Nie, 1996), Baluntai-Sangshuyuanzi Fault (Li et al., 2020; B. Wang et al., 2018;
17
18
19 825 Yang et al., 2007; Zhong et al., 2015) and the Main Tianshan Shear Zone (Laurent-Charvet et al.,
20
21 826 2002, 2003; Shu et al., 2002). Our field observations show that pre-Permian rocks and structures
22
23
24 827 in the Kerguty (D_{K2-2} and D_{K3-2}) and Chahan-Wusu (D_{Ch-2}) (Fig. 2, 3b, 6 and Table 1) sections
25
26 828 were overprinted by dextral-shearing deformation. The D_{K2-2} and D_{K3-2} events resulted from the
27
28
29 829 activity of the Baluntai Fault, and the D_{Ch-2} deformation corresponds to the Huolashan Fault (Lin
30
31 830 et al., 2013). Previous zircon U-Pb and mica ⁴⁰Ar/³⁹Ar dating in the mylonites constrained the
32
33
34 831 timing of this regional dextral strike-slip shearing in the Tianshan Orogen at 305-244 Ma (de Jong
35
36 832 et al., 2009; He et al., 2021; Laurent-Charvet et al., 2002; Li et al., 2020; Shu et al., 2002; B. Wang,
37
38 833 Chen, et al., 2007; Zhou et al., 2001). Large Permian NW-SE and ENE-WSW dextral fault zones
39
40
41 834 in the Tianshan domain are regarded as an effect of lateral extrusion that occurred after the
42
43 835 Carboniferous final convergence between Tarim and Tianshan (de Jong et al., 2009; Konopelko et
44
45 836 al., 2013; Rolland et al., 2013; B. Wang, Chen, et al., 2007). Incidentally, the Permian transcurrent
46
47
48 837 tectonics reactivated several Paleozoic sutures that acted as zones of weakness (Fig. 16).

50 838 5.4 Tectonic Evolution and Updated Geodynamic Model

51
52
53 839 For a long time, due to the disagreement on three key scientific issues concerning the
54
55 840 tectonic evolution of the STS and its adjacent units, various geodynamic models have been
56
57
58 841 proposed. They can be divided into two categories: (1) the large accretionary wedge model of
59

65

842 continuous northward subduction (Gao et al., 1998; Gao & Klemd, 2003; Han et al., 2011; Xiao
843 et al., 2013); (2) two-stage subductions with opposed vergence (Gao et al., 2011; Ge et al., 2014;
844 Han et al., 2015; Jiang et al., 2014) or southward subduction (Charvet et al., 2007, 2011; Loury et
845 al., 2015, 2016; Shu et al., 2002; B. Wang et al., 2008, 2011b, 2018) based on trench-arc-basin
846 system. The former regards the STS as an accretionary complex with southward thrusting in which
847 the southern ophiolite mélangé zones are klippen transported from the northern Akyazi belt (Gao
848 et al., 1998; Xiao et al., 2013). However, this model cannot account for many geological facts,
849 such as the existence of a Paleozoic active continental margin of the northern Tarim craton (Ge et
850 al., 2012, 2014; Lin et al., 2013; Zhu, Li, Dong, Wang, et al., 2008), the top-to-the-north kinematics
851 in these mélangé zones (Charvet et al., 2007, 2011; Lin et al., 2009; Shu et al., 2002; B. Wang et
852 al., 2010, 2011b, 2018). The two-stage subduction model was proposed based on the spatio-
853 temporal distribution of arc magmatism and detrital zircon provenance analyses; i.e., bidirectional
854 or southward subduction of the South Tianshan Ocean during the early Paleozoic switched into
855 northward subduction during the late Paleozoic (Gao et al., 2011; Ge et al., 2014; Han et al., 2015;
856 Jiang et al., 2014). Our new research data covers multiple aspects such as arc magmatism, detrital
857 zircon provenances, regional structures and migmatization. These results consistently support the
858 Paleozoic southward subduction of the PTO and opening of the South Tianshan back-arc basin.
859 Combined with previous results, the Paleozoic tectonic evolution of the Central and South
860 Tianshan can be integrated as follows:

(a) Early-middle Paleozoic subduction of the PTO and back-arc extension

862 The subduction of PTO beneath the CTS-Tarim during the Ordovician to Early Devonian
863 (ca. 480-390 Ma) generated continental arc magmatism in the CTS (Baluntai area), STS (Kaidu-
864 Kuikewusu and Huolashan areas) and northern Tarim (Gao et al., 2012; Ge et al., 2014; Lin et al.,

865 2013; Shi et al., 2007; Zhong et al., 2015, 2019). Similarly, the ca. 500-410 Ma calc-alkaline
866 magmatism that occurred along the southern margin of the Yili block, is interpreted to result from
867 northward subduction of the PTO based on regional structural analysis (Han et al., 2011; Xu et al.,
868 2013); thus, a divergent bidirectional subduction of the PTO is suggested (Alexeiev et al., 2015;
869 Cao et al., 2017; Gao et al., 2009; Han et al., 2015; Zhong et al., 2017). The tectonic transition
870 from advancing to retreating subduction happened during ca. 440-390 Ma and induced the opening
871 of the South Tianshan back-arc basin (Table S4 and references therein) and progressive decrease
872 of arc-related magmatism in the STS (Fig. 13a and 17a) (Charvet et al., 2011; Han et al., 2016;
873 Liu et al., 2022).

874 Several lines of evidence support this tectonic transition and suggest that it likely lasted
875 until the Carboniferous: (1) ca. 409-407 angular unconformity and ca. 370-320 Ma subduction-
876 related magmatism in extensional setting in the Baluntai area of the CTS (Fig. 2 and 13) (Dong et
877 al., 2011; Jin et al., 2014; Ma et al., 2014; X. S. Wang et al., 2021; Yin et al., 2017; Zhong et al.,
878 2015); (2) Devonian-Carboniferous massive carbonate and turbidite deposition in the STS and
879 northern Tarim (Allen et al., 1993; Gao et al., 1998; XBGMR, 1993); (3) late Silurian-Devonian
880 extensional structures in northern Tarim (Li et al., 2015); (4) early Carboniferous (ca. 341-332 Ma)
881 granulite-facies metamorphism and coeval E-MORB and OIB-like dolerite dykes in the Yushugou
882 area, linked with asthenosphere upwelling (Jian et al., 2013); (5) supra-subduction zone setting of
883 all the ophiolitic rocks in the southern mélangé belt of the STS (Dong et al., 2005; Jiang et al.,
884 2014; Long et al., 2006; B. Wang et al., 2011b, 2018; C. Wang et al., 2009); and (6) opening of
885 the Wuwamen-Guluogou back-arc basin at ca. 334 Ma (Dong et al., 2005; Jiang et al., 2014). In
886 addition, because the STS ophiolites cover a large age span of ~100 Ma, are discontinuously
887 distributed and separated by several carbonate platforms, they were deemed to represent multiple

1
2
3
4 888 back-arc basins, which opened and closed separately and diachronously (B. Wang et al., 2018;
5
6 889 Zhong et al., 2019), analogous to the present West Pacific.

8
9 890 (b) Closure of oceanic basins and amalgamation of Yili-CTS-Tarim (ca. 380-310 Ma)

10
11 891 After the closure of the PTO (ca. 345-320 Ma), continental collision took place between
12
13
14 892 the Yili and CTS blocks from the Late Devonian to early Carboniferous. It resulted in HP/UHP
15
16 893 metamorphism and was accompanied by top-to-the-north ductile thrusting in the Atbashi-Akyazi-
17
18
19 894 Mishigou-Gangou belt (Gao & Klemd, 2003; Lin et al., 2009; Loury et al., 2015; B. Wang et al.,
20
21 895 2010). Meanwhile in the South Tianshan, the diachronous closure of back-arc basins represented
22
23
24 896 by ophiolitic mélanges in the Kulehu-Misibulake (ca. 359-356 Ma), Yushugou-Tonghuashan
25
26 897 (before ca. 325 Ma) and Wuwamen-Guluogou (before ca. 304 Ma) areas (B. Wang et al., 2011b;
27
28
29 898 L. Zhang et al., 2018 and this study) resulted in re-welding/collision of the CTS and Tarim (Shu
30
31 899 et al., 1997; B. Wang et al., 2011b; Zhong et al., 2015, 2019 and this study), giving rise to the top-
32
33
34 900 to-the-north thrusting preserved in both CTS and STS and south-directed back-thrusting in the STS
35
36 901 (Fig. 17b).

37
38 902 The absence of ca. 370-320 Ma arc magmatism and detrital zircons in Carboniferous strata
39
40
41 903 of the STS and northern Tarim is usually considered as the argument against the southward
42
43 904 subduction model (e.g., X. S. Wang et al., 2018). However, the absence of subduction-related
44
45
46 905 magmatism may be due to the narrowness of back-arc basins whose slabs are not large enough to
47
48 906 reach the depth of dehydration melting, similarly to the Western Alps in the Oligocene (Handy et
49
50
51 907 al., 2010).

52
53 908 (c) Post-orogenic extension with crustal anatexis (ca. 305-295 Ma)

54
55 909 During the late Carboniferous, post-collisional extension induced the top-to-the-south
56
57
58 910 detachment in the Atbashi-Akyazi areas associated with the exhumation of HP/UHP metamorphic

911 complex (Jourdon et al., 2017; Loury et al., 2015; B. Wang et al., 2010), which represents the
912 continental-derived units previously underthrust beneath the CTS-Tarim. In the latest
913 Carboniferous, the supracrustal rocks buried at middle-lower crustal level due to the collision
914 between the CTS and Tarim underwent migmatization, and then were exhumed via regional
915 tectonic extension in the STS, such process is linked to late or post-orogenic collapse of the
916 previously thickened crust (Fig. 3 and 17c). Meanwhile, previous studies indicated that post-
917 collisional magmatism largely contaminated by the Meso-Neoproterozoic continental crust widely
918 developed in the Tianshan, and then to the Permian, a remarkable input of mantle material
919 contributed significantly to the formation of juvenile crust, in possible connection with the slab
920 breakoff following the collision (Fig. 13) (Konopelko et al., 2007; Ma et al., 2015; Ni et al., 2021;
921 Seltmann et al., 2011; B. Wang et al., 2009; Yu et al., 2020). A note of caution is due here that
922 upper extensional structures are usually reworked by later tectonism or not preserved due to
923 denudation.

(d) Latest Carboniferous to Permian transcurrent tectonics

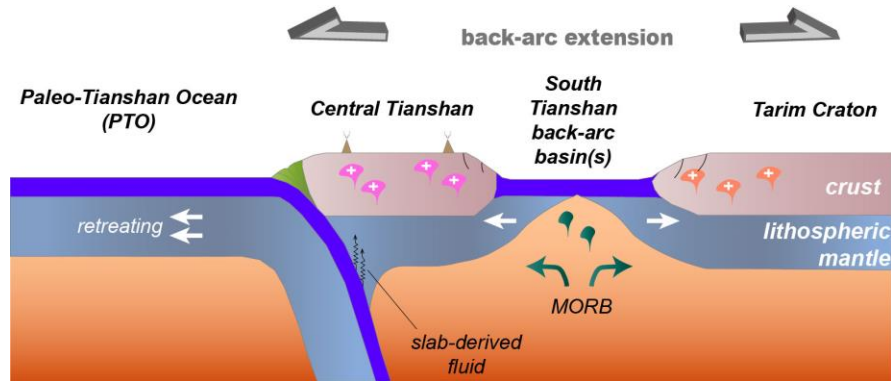

925 Oblique convergence between the major tectonic units induced strike-slip ductile shearing
926 along their boundaries after their primary amalgamation. The latest Carboniferous to Permian
927 dextral faulting marked the conversion from subduction-accretion into intracontinental
928 transcurrent tectonics (He et al., 2021; Laurent-Charvet et al., 2002; Li et al., 2020; Shu et al.,
929 1999; B. Wang et al., 2007). These dextral strike-slip shear zones intensively overprinted the
930 earlier structures in accretionary wedges, ophiolitic mélangé zones and magmatic arcs, as it can be
931 observed along the Baluntai Fault (Fig. 3). Paleomagnetic evidence show that orogen-parallel
932 dextral motion occurred along the boundaries of major tectonic units such as the Yili block, Tu-
933 Ha basin and Tarim craton (B. Wang, Chen, et al., 2007; X. Zhu et al., 2018, 2019). In addition,

934 early Permian post-orogenic alkaline magmatism was well developed within or near the regional
935 ductile shear zones, in likely connection with local transtension (B. Wang et al., 2009, 2014).

936 Overall, two stages of extensional tectonics, i.e., back-arc spreading triggered by the early-
937 middle Paleozoic retreating subduction (Fig. 17a) and latest Carboniferous gravitational collapse
938 with crustal anatexis (Fig. 17c), complement crucial scenes and details to replay the tectonic
939 evolution of the Paleozoic Tianshan Orogen. In addition, our results and the new model may have
940 implications for knowledge of the flow of anatectic crust in the accretionary orogens, and provide
941 a geological instance of how accretionary orogens evolve from a western Pacific-type subduction
942 system to post-orogenic thinning and partial-melting of the thickened crust.

(a) Back-arc extension resulted from subduction of the PTO (snapshot at ca. 420 Ma)

(b) Closure of oceanic basins and re-amalgamation of CTS-Tarim (snapshot at ca. 310 Ma)

(c) Post-orogenic extension with crustal anatexis (snapshot at ca. 300 Ma)

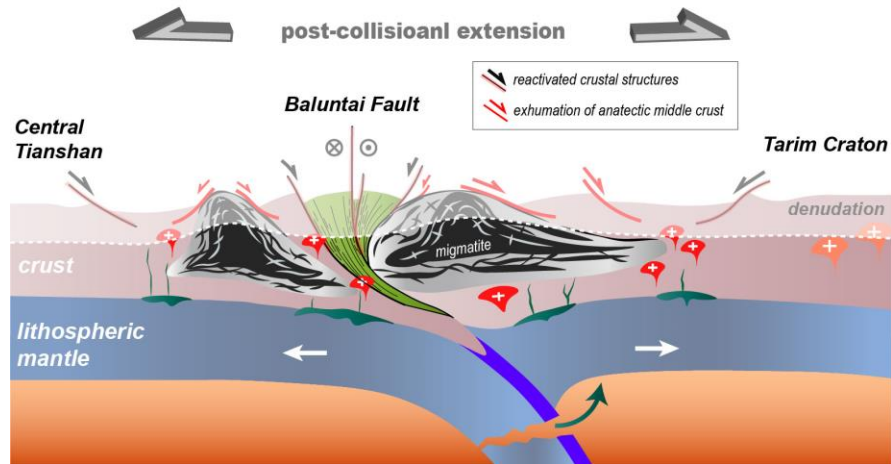

Fig. 17 Simplified geodynamic model showing the Paleozoic tectonic and magmatic evolution of the Central and South Tianshan (modified from [Zhong et al., 2019](#)). (a) Silurian-Early Devonian retreating subduction of the Paleo-Tianshan Ocean resulted in the opening of the South Tianshan back-arc basin, and separation of the Central Tianshan from the Tarim craton, associated with extensional magmatism. (b) From

948 Late Devonian to Carboniferous, continental collision occurred after the subduction and closure of the
949 oceanic basins; subduction and collision triggered thrusting, folding, crustal thickening and HP/UHP
950 metamorphism. Please see [B. Wang et al. \(2018\)](#) for detailed evolution of the South Tianshan back-arc
951 basin. (c) During the latest Carboniferous-early Permian, the thickened crust underwent anatexis to and
952 exhumation under an extensional setting that triggered the orogenic collapse (CTS anatexis of [Zhong et al.,](#)
953 [2015](#)), meanwhile, partial melting of the ancient crust generated high-potassium peraluminous granites with
954 post-collisional characteristics (see seismic profiles in [He et al., 2016](#)).

956 **6. Conclusions**

957 (1) Field observations and structural analysis reveal that top-to-the-north ductile shearing
958 structures preserved both in the CTS arc-type meta-igneous rocks and STS meta-sedimentary rocks,
959 most likely correspond to the Late Devonian to Carboniferous southward subduction of the South
960 Tianshan back-arc basins. These tectonic structures were overprinted by north- and south-verging
961 brittle-ductile thrust faults and folds in the CTS and STS, respectively; forming a positive flower-
962 structure interpreted to result from the late Carboniferous CTS-Tarim collision following the
963 closure of back-arc basins.

964 (2) The sedimentary and volcanoclastic rocks in the Kerguty and Chahan-Wusu sections
965 were deposited in the STS back-arc basins and then deformed and variously metamorphosed
966 during the closure of the back-arc basins. Our new detrital zircon dating results constrain the
967 depositional ages of these meta-sedimentary and volcanoclastic rocks between 421 Ma and 392
968 Ma. Paleozoic and Precambrian detrital zircons were diagnostically derived from the CTS and
969 northern Tarim magmatic arcs.

970 (3) The ductilely deformed granitoids and metavolcanic rocks from the Kerguty and
971 Chahan-Wusu sections belong to the metaluminous and calc-alkaline series, and were formed in
972 the continental arc of the Central and South Tianshan during the Silurian-Early Devonian. Based
973 on our new results and previously published data, the opening of the STS back-arc basins between

974 the CTS continental arc and northern Tarim resulted from the southward retreating subduction of
975 the Paleo-Tianshan Ocean.

(4) Late Carboniferous migmatites in the STS are studied for the first time. Our new zircon
U-Pb age of the leucogranite dykes indicate that anatexis occurred at ca. 304 Ma, which may
represent the later period of a protracted crust melting. Ductile deformation structures in the
migmatites suggest that N-S extension dominated the STS during the latest Carboniferous, which
triggered the exhumation of anatectic mid-lower crust. Such extension and associated
migmatization may represent the post-orogenic gravitational collapse of the STS. Our new results
combined with the literature data suggest that undeformed high-potassium peraluminous granites
(ca. 305-295 Ma) could be genetically associated with the migmatites. Thus, termination of the
South Tianshan orogeny is constrained at the Carboniferous-Permian boundary.

(5) Pre-Permian rocks and structures were overprinted by dextral strike-slip ductile
shearing along the STS-CTS boundary (i.e., the Baluntai Fault), and also by Cenozoic south-
verging brittle thrust faults in the STS-Tarim transition zone.

Acknowledgments

We appreciate Mr. B. Wu for his kind help in the zircon LA-ICPMS dating. Ms. W. Pu and H. Z.
Wei (NJU) helped with whole-rock geochemical analyses. This study was cosponsored by the
National Natural Science Foundation of China (Grants: 42161144013 and 41772225), the
Fundamental Research Funds for the Central Universities (Grant: XJ2022001001). The financial
supports by the China Scholarship Council (CSC: 202206190021; 202206190193) are appreciated
for the research stay of X.H. Ni and T.T. Cao in France.

Table S7 Statistics of descriptions of ductile deformation kinematics in the Central and South Tianshan.

Introduction

The supporting information includes the analytical methods, five figures and seven tables. The analytical methods consist of detailed procedures for zircon U-Pb dating and whole-rock major and trace element test. Figure S1 is a supplementary field photo for the studied Chahan-Wusu section. Figures S2 to S5 show cathodoluminescence images of the zircons from the studied samples. Table S1 to S3 present original data of the tested samples in this paper. Table S4 to S6 compile published radiometric ages and zircon Hf isotopic data for Paleozoic magmatic rocks, as well as detrital zircon U-Pb ages from Silurian-Carboniferous clastic rocks of the South Tianshan and adjacent areas. Table S7

present statistics of available structural data of ductile deformation in the Central and South Tianshan.

Analytical methods

LA-ICP-MS zircon U-Pb dating

The rock samples were processed as follows to obtain zircon grains: rock sample crushing, powder sorting, heavy liquid separation, and electric and magnetic separation, followed by handpicking euhedral, colorless zircons without fractures under a binocular microscope. Thereafter, the zircon grains were mounted in epoxy resin and polished and carbon-coated for subsequent cathodoluminescence (CL) imaging and U-Pb analyses. The CL imaging of zircons was conducted using the Gatan MonoCL 3+ Fluorescence Spectrometer at the State Key Laboratory of Continental Dynamics, Department of Geology, Northwest University, Xi'an, China.

Zircon dating was conducted at different laboratories. Zircons from four samples of the Chahanwusu section (12TS62-3, 12TS68-2, 12TS69-1 and 12TS62-1) and six samples (12TS73-1, 12TS73-2, 12TS74, 12TS77-2, 12TS93-1 and 12TS98) of the Kerguty section were analyzed on a VG PQ quadrupole Multi-Collector Inductively Coupled Plasma Mass Spectrometry (MC-ICP-MS) (Nu Instruments, Wrexham, UK) that was equipped with a New Wave Research ultraviolet (UV) 193 nm laser-ablation system at the Department of Earth Sciences, University of Hong Kong, Hong Kong, China. Three analyses on the 91500 external standard zircon ([Wiedenbeck et al., 1995](#)), two analyses on the GJ internal standard zircon (608.5 ± 1.5 Ma; [Jackson et al., 2004](#)), and one analysis on a monitor NIST SRM 610 standard were performed before and after the experiment for each individual rock sample, and the 91500 external standard zircon and GJ internal standard zircon were analyzed twice every 10 analyses throughout the experiments. The off-line selection and integration of background and analytical signals and the time drift correction and quantitative calibration of U-Pb dating were performed with ICPMSDataCal ([Liu et al., 2008](#)).

Samples from the migmatitization domain of the Kerguty section (12TS95, 12TS82-1, 12TS82-3 and 12TS80-2) were dated on an Qtegra ICPMS that was attached to a New Wave 193 nm laser-ablation system with an in-house sample cell at the State Key Laboratory for Mineral Deposits Research (Nanjing University, Nanjing, China). Each batch of 15 zircon samples was analyzed together with four GJ internal standard zircons (608.5 ± 1.5 Ma; Jackson et al., 2004) and one Mud Tank external standard zircon (732 ± 5 Ma; Black & Gulson, 1978) to control the instrument stability and analytical accuracy. The U-Pb ages were calculated using the online software package GLITTER (ver. 4.4; [http:// www.mq.edu.au/GEMOC](http://www.mq.edu.au/GEMOC)). Common-Pb correction was performed using the Microsoft Excel embedded program ComPbCorr#3 15G (Andersen, 2002).

Whole-rock major and trace element

The major elements were determined using X-ray fluorescence (XRF) at the Modern Analysis Center, Nanjing University, Nanjing, China. The details of the analytical procedures are similar to those described by Couture et al. (1993). Trace elements, including rare earth elements (REEs), were analyzed at the State Key Laboratory for Mineral Deposits Research at Nanjing University by using an HR-ICPMS (Finnigan Element II). The analytical procedures and equipment were reported by Gao et al. (2003). The analytical errors were 0.5%-3% for major elements and 0.7%-5% for trace elements.

Notes:

a. Concordance = $1 - \frac{\text{abs}((^{207}\text{Pb}/^{235}\text{U}) - (^{206}\text{Pb}/^{238}\text{U}))}{(^{206}\text{Pb}/^{238}\text{U})}$

b. Discordant results: concordance < 90% and error ratios > 5%.

c. $^{207}\text{Pb}/^{206}\text{Pb}$ and $^{206}\text{Pb}/^{238}\text{U}$ ages were adopted during calculation and illustration of analyses with apparent ages above and below 1000 Ma, respectively.

Note:

- References are consistent with that in the Table S4.
- The calculation formulas are as follow:

$$e_{\text{Hf}}(0) = \left(\frac{{}^{176}\text{Hf}/{}^{177}\text{Hf}}{\left(\frac{{}^{176}\text{Hf}/{}^{177}\text{Hf}}{\text{CHUR},0} - 1 \right)} \right) \times 10000,$$

$$f_{\text{Lu/Hf}} = \left(\frac{{}^{176}\text{Lu}/{}^{177}\text{Hf}}{\left(\frac{{}^{176}\text{Lu}/{}^{177}\text{Hf}}{\text{CHUR}} - 1 \right)} \right)$$

$$e_{\text{Hf}}(t) = \left(\frac{{}^{176}\text{Hf}/{}^{177}\text{Hf}}{\left(\frac{{}^{176}\text{Hf}/{}^{177}\text{Hf}}{\text{CHUR},0} - \left(\frac{{}^{176}\text{Lu}/{}^{177}\text{Hf}}{\text{CHUR}} \times (e^{\lambda t} - 1) \right) \right)} \right) \times 10000$$

$$T_{\text{DM1}}(\text{Hf}) = 1/\lambda \times \ln \left(1 + \left(\frac{{}^{176}\text{Hf}/{}^{177}\text{Hf}}{\text{DM}} - \left(\frac{{}^{176}\text{Lu}/{}^{177}\text{Hf}}{\text{DM}} \right) \right) / \left(\frac{{}^{176}\text{Hf}/{}^{177}\text{Hf}}{\text{S}} - \left(\frac{{}^{176}\text{Lu}/{}^{177}\text{Hf}}{\text{DM}} \right) \right) \right)$$

$$T_{\text{DM2}}(\text{Hf}) = T_{\text{DM1}}(\text{Hf}) - (T_{\text{DM1}}(\text{Hf}) - t) \left(\frac{f_{\text{CC}} - f_{\text{S}}}{f_{\text{CC}} - f_{\text{DM}}} \right)$$

where, $\left(\frac{{}^{176}\text{Lu}/{}^{177}\text{Hf}}{\text{S}} \right)$ and $\left(\frac{{}^{176}\text{Hf}/{}^{177}\text{Hf}}{\text{S}} \right)$ are the measured values of samples; $\left(\frac{{}^{176}\text{Lu}/{}^{177}\text{Hf}}{\text{CHUR}} \right) = 0.0336$
and $\left(\frac{{}^{176}\text{Hf}/{}^{177}\text{Hf}}{\text{CHUR},0} \right) = 0.282785$ (Bouvier et al., 2008);
 $\left(\frac{{}^{176}\text{Lu}/{}^{177}\text{Hf}}{\text{DM}} \right) = 0.0384$ and
 $\left(\frac{{}^{176}\text{Hf}/{}^{177}\text{Hf}}{\text{DM}} \right) = 0.28325$ (Griffin et al., 2000); $f_{\text{CC}} = -0.548$ (average continental crust), $f_{\text{DM}} = 0.16$,
 $t =$ crystallization time of zircon, $\lambda = 1.867 \times 10^{-11} \text{yr}^{-1}$ (Scherer et al., 2001) are used in calculation.

Table S7 Statistics of descriptions of ductile deformation kinematics in the Central

Index No.	Region	Foliation (strike/dip)	Lination (trend/plunge)
1	Baluntai	ENE-WSW/steeply	
1	Kerguty	ENE-WSW/steeply N	
1	Kerguty	WNW-ESE/steeply	WNW/steeply
1	Chahan Wusu	WNW-ESE/subvertical	
2	Kuikewusu	E-W/SSE	
2	Kaidu	ENE-WSW/ steeply	NNW/ steeply
2	Kuikewusu	ENE-WSW/ subvertical	ENE-WSW/ Subhorizontal
2	Kuikewusu	ENE-WSW/ subvertical	ENE-WSW/ Subhorizontal
3	Mishigou	WNW-ESE/SSW 40°~65°	SE/moderately
3	Mishigou	WNW-ESE/subvertical	WNW-ESE/subhorizontal
4	Wuwamen ophiolite mélange	WNW-ESE/SSW 20°~70°	SW/downdip
4	Wuwamen ophiolite mélange	WNW-ESE/SSW 60°~80°	NW-SE/subhorizontal
5	Baluntai	WNW-ESE/S 30°~60°	SE/steeply
5	Baluntai	WNW-ESE/subvertical	WNW-ESE/subhorizontal
6	Akeyazi	ENE-WSW/ N	NW-SE/ moderately to steeply
7	Heiyinshan	E-W/ gently S	N-S to NW-SE
7	Kulehu	E-W/ variably	
8	Akeyazi	ENE-WSW/ N	NE/ moderately to steeply
9	Kekesu	ENE-WSW/ SE	SE to SW/ subhorizontal to moderately
9	Kekesu	ENE-WSW/ SE	SSE/ steeply
10	Akeyazi	refolded	NW-SE
10	Akeyazi	NE-SW to ENE- WSW/S	N-S

10	Akeyazi		subvertical
10	Akeyazi	NE-SW/subvertical	subhorizontal
11	Aqikuduke-Weiya	E-W/S	SSW to SSE/steeply
11	Aqikuduke-Weiya	E-W/subvertical	E-W/ subhorizontal
12	northern margin	ENE-WSW/S ~52°	SE/ ~45°
12	Kumishi-Hongliuhe	E-W/S ~60°	SSE/ ~46°
12	Kumishi-Hongliuhe	E-W/steeply S	W/subhorizontal
12	southern margin		
13	Kekesu	ENE-WSW/ SSE	NNW/ variably
14	Atbashi Range	W-E/S 40°~70°	
14	Pobeda Massif	ENE-WSW/ SSE-SSW 70°~80°	
14	Atbashi Range	W-E/S ~30°	
15	Atbashi Range	W-E/ N (detachment fault zone)	
16	Bogda Shan	ENE-WSW/ S 65°	
17	Harlik	NW-SE/NE 55°~80°	SW/downdip
18	Liushugou	vertical	WNW-ESE/subhorizontal
19	north margin of CTS	E-W/subvertical	subhorizontal
19	south margin of CTS	E-W/S	W/subhorizontal
19	Xinger	E-W/subvertical	subhorizontal
20	Kekesu	ENE-WSW/ steeply S	SSE/ steeply
21	Kekesu	ENE-WSW/ steeply SE	ENE to WSW/ Subhorizontal
22	Nalati		

Notes:

- Deformation events in green represent Late Devonian to Carboniferous compression, in grey represent other periods.
- Index numbers correspond to that in the Figure 17.
- Abbreviations: NTS--the North Tianshan; CTS--the Central Tianshan; SYB--the southern Yili block.

and SouthTianshan.

Features/indicators	Sense of deformation	Timing	Tectonic Unit
sigmoidal boudins of early felsic dyke, Z-type interlayered folds	top-to-the-north	D ₃ -C ₁	CTS
asymmetric fold and axial plane foliation	southward thrusting	D ₃ -C ₁	STS
north: microscale oblique foliation of quartz indicates top-to-the-north shearing; south: asymmetric folds indicate S-directed extension	N-S extension	C ₂	STS
crenulation of the foliation with steeply WNW-dipping hinge, close to the strike-slip zone	E-W dextral	P	STS
asymmetric tight folds with axial-planar schistosity, sigmoidal quartz boudins	top-to-the-north	D-C ₁	STS
σ-type K-feldspar porphyroclasts, recrystallized quartz clasts, asymmetric biotite pressure shadows	top-to-the-north	D-C ₁	STS
mylonitization along several localized strike-slip faults, σ-type feldspar and quartz porphyroclasts	E-W dextral	C ₂ -P ₂	STS
sigmoidal recrystallized quartz porphyroclasts and asymmetrically elongated biotite	E-W sinistral	P	STS
S-C fabric, asymmetric lenses	top-to-the-north	C ₁	CTS
asymmetric fabrics	E-W dextral	P	CTS
asymmetric deflection of the foliation around an isolated sigmoid boudin in a mylonitic marble, rotated feldspar porphyroclasts, oblique foliation, bookshelf structure	top-to-the-north	C	STS
mylonitic foliation, σ-type pebbles and quartz porphyroclasts	dextral	P	STS
σ-type quartz and feldspar phenocrysts, asymmetric biotite pressure shadows	top-to-the-north		CTS
sigmoid K-feldspar with mica pressure shadow, oblique boundaries of quartz sub-grains with respect to the main foliation	WNW-ESE dextral	P	CTS
		C ₁	STS
fibrous quartz or calcite pressure shadows crystallized around sigmoid limestone clasts within the sheared matrix	top-to-the-north	D ₃ -C ₁	STS
shear bands and intrafolial asymmetric folds within the melange matrix along with sigmoidal volcanic rock clasts	top-to-the-north	D ₃ -C ₁	STS
		C ₁	STS
asymmetric plagioclase porphyroclasts, shear bands of muscovite	top-to-the-north	D ₃ -C ₁	STS
sigmoidal muscovite and recrystallized quartz ribbons with an oblique grain-shaped fabric	south-directed shearing	C ₂	STS
sigmoidal lenses of eclogite blocks and quartz veins	top-to-the-NW	C ₁	STS
sigmoidal quartz veins and shear bands	northward thrusting	C ₁	STS

S-verging or SE-verging synforms and antiforms, sigmoidal lenses of eclogite and mafic lava	top-to-the-south	C ₂	STS
σ-type, δ-type porphyroblast, mica fish, etc.	dextral	P	STS
asymmetric folds and microstructures	northward thrusting	D	CTS-STS
	dextral	P ₂	CTS-STS
	northward thrusting	D	CTS
	northward thrusting	D	STS
	sinistral	D	STS
	southward decollement	C ₂ -P ₁	CTS
A-type shearing folds	SSE to NNW thrusting	C ₁	STS
	top-to-the-north thrusting	C	STS
	top-to-the-north thrusting	C	STS
	top-to-the-south detachment	C ₂	STS
	top-to-the-south detachment	C ₂	STS
olistostrome formation, south-verging asymmetric folds	NNE-SSW extension	C ₂ -P ₁	NTS
	NW-SE extension	C ₂	NTS
quartz and feldspar rotated porphyroblasts	dextral strike-slip	P	STS
quartz and feldspar rotated porphyroblasts	dextral strike-slip	P ₁ -P ₂	CTS
S-C fabric, σ-shaped dikes	dextral strike-slip	P ₁	CTS
	dextral strike-slip	P ₁	STS-NTC
	dextral strike-slip	P ₂	SYB
drag folds and asymmetric boudins, σ- and δ-type porphyroclasts of feldspar or pyroxene, etc.	dextral strike-slip	P ₂	STS
	dextral strike-slip	P ₁	SYB

resent late Carboniferous post-collisional extension, and in blue represent Permian strike-slip shearing.

ock; STS--the South Tianshan.

(a) Back-arc extension resulted from subduction of the PTO (snapshot at ca. 420 Ma)

(b) Closure of oceanic basins and re-amalgamation of CTS-Tarim (snapshot at ca. 310 Ma)

(c) Post-orogenic extension with crustal anatexis (snapshot at ca. 300 Ma)
